maiden-cane [maidencane] (perhaps meaning “grass resembling harvest maiden,” from the old tradition of forming the last handful of wheat into the shape of a woman; harvest maiden also known as kirm-baby and kirm-doll, from the 1770s but surely much older as “kirm” dates to the 1300s, USA)

*pahitotpifi* (*pahi*, grass, *totpiti*, knees, Mikasuki); [*pahitôtpitô:cî*] (*pahi*, grass, *totpiti*, knees, *oci*, small, Mikasuki)

***Panicum hemitomon*.** From Institute of Food and Agricultural Sciences.

***Panicum laxiflorum*** (loosely flowered) (as *P. xalapense*)  
 (= *Dichantherium laxiflorum*)  
 open-flower witch-grass [openflower witchgrass] (Florida)  
 soft-tufted panic-grass [soft-tufted panicgrass]

***Panicum strigosum*** (with appressed hairs) (as *P. polycaulon*)  
 (= *Dichantherium strigosum*)  
*cofímassi* (*cufe*, rabbit, *em*, its, *vsse*, dried leaves, Creek); *cokfímasi* (*cokfí*, rabbit, *im*, its, *híssi*, leaves, Koasati); *cokfímpatâ:kî* [*tcokfwimpataki*] (rabbit's bed, Mikasuki)  
 cushion-tufted panic-grass [cushion-tufted panicgrass]  
 rough-hair witch-grass [roughhair witchgrass] (Florida)

Hogan (1978) found pollen of *Panicum hemitomon* in the coprolites of the Glades people that she studied. As they were living beside vast stands of the windpollinated plants, that is no clear indication that they used the grass. However, being in a pre-Columbian context and having historical documentation of use is provocative. The Seminoles too

know these formerly abundant grasses (Sturtevant 1955), and at least use them to the extent of “reading” the landscape. Where there is *pahitófpitó:ci*, they know that the water remains near a certain depth. That constitutes part of their knowledge of the landscape.

Because of doubtful identifications, Moerman (1998) placed all the grasses used by the Creeks, Natchez, and Seminoles under *Panicum* sp. However, the species recorded by Sturtevant (1955) are reliably known. Since Sturtevant (1955) indicated that a third species was similarly used, perhaps others were used by the Seminoles’ relatives, the Creeks.

The Creeks and Natchez used a *Panicum* leaf infusion for fevers, especially malaria (Swanton 1928a, Taylor 1940). Symptoms of those diseases are close enough to the Seminole malady called “Gopher Tortoise Sickness” (cough, dry throat, noisy chest) to suggest that the Creeks and Natchez used the same grasses. The Seminoles also used *cokfimpatâ:ki* for “Rabbit Sickness” (muscle cramps) (Sturtevant 1955).

The Cherokee used some *Panicum*, possibly more than one species, for padding inside their moccasins (Hamel and Chiltoskey 1975).

### *Parietaria*

(Linnaeus based this on Latin *parietis*, a wall, in reference to its frequent occurrence there)

bartram [bertram] (an English corruption of Greek *pyrethrum*, from *pyros*, fire; the name was originally given to *Anacyclus pyrethrum* or pellitory of Spain by at least 1578 with Henry Lyte’s translation of Dodoens’s *Cruydeboek* of 1554; later the name became secondarily applied to *Parietaria*, because both were called pellitory)

*blidnesle* (gentle nettle, Norwegian)

*Glaskraut* (glass herb, German)

*lus a’ bhalla* (wall herb, Gaelic)

*parietaria* (from Latin *parietis*, Italian, Spanish); *parietária* (Portuguese); *pariétarie* (French); pellitory (from Latin *parietis*)

***Parietaria floridana*** (from Florida)

*herbe à murailles* (wall herb, Haiti)

*herbe gras* (fat herb, Haiti)

*paille à terre* (country straw, Haiti)

***Parietaria floridana*.** a. Section of plant, b. Flower, side view, c. Flower, longitudinally dissected, d. Fruit, e. Achene. f. Floral diagram. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*parietaria* (pellitory, Dominican Republic); *pariétarie* (pellitory, Haiti); *pariétarie capitee* (pellitory with heads, Haiti); *pariétarie sauvage* (wild pellitory, Haiti); pellitory (Florida)  
*thé del malheureux* (tea for the unfortunate, Haiti)

Newcomers to the New World were able to recognize this southeastern plant because they knew European “pellitory-of-the-wall” or “mind-your-own-business” (*Paritaria judaica* in western and southern Europe and *P. officinalis* in central and southern Europe). *Parietaria officinalis* was famous and was known in 16th-century English as parietorior or pellitoire of the wall, in German as *Tag und Nacht* (day and night), *Sonet Peterskraut* (St. Peter’s herb), *Glaszkraut* (glass herb), or Dutch *glascruyt* (glass herb). Keeping closer to the Latin, the French said *parietaire* or *laparitoire*, the Italians and Spanish *parietaria*. Old World people took their use from classical authors Dioscorides (fl. A.D. 40–80), Galen (ca. A.D. 129–ca. 199), and Aëtius (A.D. 527–565), and used it for kidney stones, as a diuretic, and to treat hemorrhoids (Meyer et al. 1999). Finding a similar plant in the Americas, they used it largely for the same problems.

In Hispaniola, fresh *P. floridana* is diuretic and is also used for painful hemorrhoids (Liogier 1974). Haitians consider an infusion of the plant a diuretic for use in treating angina and gout (Morton 1981). *Parietaria* is also used for erysipelas and earache.

***Parthenocissus***

(Jules Emile Planchon, 1823–1888, combined Greek *parthenos*, virgin, and *kissos*, ivy, perhaps alluding to the unisexual flowers)

***Parthenocissus quinquefolia*. Drawn  
by P.N.Honychurch.**

*Jungfraurebe* (virgin vine, German); *vigne-vierge* (virgin vine, French)  
*vite del Canada* (Canada grape, Italian)

***Parthenocissus quinquefolia* (with five leaflets)**

American ivy

false grape; *parrita cimarróna* (little wild grape)

five-leaves; *l'herb à cinq feuilles* (five-leaved herb, Houma, Louisiana)

*ifā imittó* (*ifā*, dog, *im*, its, *ittó*, tree, Koasati)

*ingtha hazi itai* (ghost grapes; *hazi*, grapes, Omaha-Ponca)

*manido'bima'kwud* (*manido*, spirit, Ojibwa)

*omakaski'bag* (toad weed, Potawatomi)

*sa-tai-al-go* (paint berries, Kiowa)  
*yfala omat* [*afala oma*] (*yfala*, poison ivy, *omat*, like, Creek)  
*vigne-vierge* (virgin vine, Quebec); Virginia [Virginian] creeper  
 (“creeper” is another word for climber or twiner)  
 woodbine [woodbind, wild wood-vine] (originally a European term for *Convolvulus* and *Hedera*, dating to about A.D. 875, and alluding to the tendency of the climbers to wrap around others, USA)

The first record of these vines in the New World is Jacques Philippe Cornutus’s *Edera quinquefolia canadensis* (five-leaved Canadian ivy), published in his book *Canadensium plantarum...historia* of 1635. Linnaeus knew this and several other sources. He had studied live plants at the *Hortus Cliffortianus*. Perhaps because he was influenced by Cornutus and others, he called the vines *Hedera quinquefolia*.

Probably the first report of interaction of the plant and people was left by Capt. John Smith in 1624. He wrote that, in Virginia, there was a “kind of woodbind...which runnes vpon trees, twining it self like a Vine: the fruit eaten...worketh...in the nature of a purge.” In spite of Smith’s report, Yanovsky (1936) said that the fruit could be eaten raw, and the stalks were peeled and boiled for food. He reported those uses in Minnesota, Montana, and Wisconsin. One of them is wrong, and I doubt that it was Smith.

Native people in the New World had long been familiar with the twiners. The plants were used by the Cherokee, Creeks, Houma, Iroquois, Jemez, Keres, Kiowa, Meskwaki, Montana tribes, Navajo, and Ojibwa (Densmore 1928, Moerman 1998). Most of these people used the plant as medicine, but they also made dye from it, and some claim to have eaten the roots. In the southeast, the Cherokee used an infusion against jaundice (Hamel and Chiltoskey 1975). The Houma used a hot decoction of stems and leaves to reduce swelling, to treat wounds, and against lockjaw (Speck 1941). The Creeks used it against venereal disease (Taylor 1940). Snow and Stans (2001) published a picture of the vine (p. 80), but gave no common name, or included it in the text. Some Seminoles still use this medicine.

In Mexico, the bark has been used as an alterative, tonic, expectorant, and against dropsy; crushed leaves are a counterirritant, producing blisters when applied to the skin (Standley 1920–1926). Early American physicians also used a tincture, which was sometimes called *Decoctum ampelopsis* or *Infusum ampelopsis*, reflecting an old scientific name, *Ampelopsis quinquefolia* (Millsbaugh 1892). Not much seemed to be known about its chemistry in the 1890s, and the same is true today. Foster and Duke (1990) cryptically wrote, “Berries reportedly toxic,” although Capt. John Smith wrote the same in the 1620s. The leaves contain calcium oxylate and cause dermatitis in some people (Foster and Duke 1990, Foster and Caras 1994), compounding the difficulty people have distinguishing between this and poison ivy (*Toxicodendron radicans*).

### *Paspalidium*

(Diminutive of *Paspalum*, Greek *paspalos*, for millet; the genus was separated from *Paspalum* by Otto Stapf, 1857–1933)

***Paspalidium geminatum*** (twins or double) (= *P. paludivagum*)  
~~akkoto: fka~~ [akkoto: rka] (akkotorkv, usually *Nelumbo*, Creek; a comparison or a misuse)

*ciktohaçi* (cekto, snake, hvce, tail, Creek)

Egyptian panicum (some consider the species native, like Allen 2003, while others think it was introduced from Egypt)

kissimmee grass (“kissimmee” was rendered as *Cacema* on the Moll Map of 1720 and *Casseeme* on William’s Map of 1837; the locality was not mentioned by Swanton in either 1939 or 1946; language and meaning unknown)

~~tołpitił~~ [pahitórpiri] (*pahi*, grass, ~~pahitótłpitił~~ knees, because the stem is jointed, Mikasuki; this name is also used for *Panicum hemitomon*, which see)

water panic grass (Florida)

Pehr Forsskål called plants he found in Egypt *Panicum geminatum* in 1775. However, it was not until 1919 that the species was transferred to *Paspalidium* in the *Flora of Tropical Africa*. Godfrey and Wooton (1979) considered the species native, while Crins (1991), Wunderlin (1998), and Diggs et al. (1999) thought it introduced. The problem is considered unsolved by Gerald Guala (personal communication, Oct. 2003).

The Seminoles use a decoction of the plant to treat “Snake Sickness” (itchy skin) (Sturtevant 1955).

### ***Paspalum***

(From Greek *paspale* or *paspalos*, meal or millet)

*Paspalum conjugatum*. Drawn by  
Mary Wright Gill From Hitchcock and  
Chase 1950.

*Paspalum conjugatum* (joined together)  
*ahan loom* (elote-roasting ear grass, Huastec)  
 bed grass (Bahamas)  
*cañamazo amargo* (big sour cane, Cuba); *cañamazo [hembra]*  
 ([female] big cane, Dominican Republic)  
*capim de marreca* (mallard hen grass, Marajó, Brazil); *capim gorda*  
 (fat grass, Marajó, Brazil)  
*gengibrillo* (little ginger)  
*grama* (grass, Dominican Republic); *grama de antena* (antenna grass,  
 Central America); *grama comun* (common grass)  
*herbe sûre [z'herbe sûre]* (sour herb, Haiti); Jamaican sour grass  
 (Jamaica); sour-grass; *yerba agria* (sour-herb)  
*horquilla* (little hairpin, Central America); *horquetilla [blanca]*  
 ([white] little hairpin, Puerto Rico); *pasto horqueta* (hairpin grass)  
*paja de panela* (sugar grass)  
*sarataya* (Siona, Ecuador)  
 sour paspalum (a book name)  
*tarurco [torurco, toro-urco]*

*trencilla* (Central America)

*turvará* (indigenous name, Costa Rica, western Ecuador)

Around the edges of wetlands where it is neither wet enough to be marsh nor dry enough to be pinelands, there is an intermediate zone locally known as wet prairie. These areas dominated by graminoid plants are where *Paspalum conjugatum* most often is encountered. The flowering scapes stand above the mostly prostrate stems and leaves, and the twobranch inflorescences have reminded people of *horquillas* (hairpins). Occasionally in *Paspalum* we find a dark mass of mycelia that has replaced the seeds, and we know that an ergot fungus (*Claviceps*) has infected the grass. Those fungi contain LSD-like chemicals and can cause problems or be used to relieve maladies. I must wonder if these grasses were used for medicines because of this fungal infection.

Judging from the names of this species throughout its range, people have had strong feelings either for or against this grass. Some pastoral groups dislike the grass because it does not provide good forage for their animals—ostensibly because of its sour taste. Others praise it highly as food for their animals. For people, though, the grass is sometimes important in remedies.

In Cuba, *cañamazo amargo* is used as a bath for patients with malaria (Roig 1945). People in Trinidad use a decoction to relieve fever, flu, pleurisy, pneumonia, and fatigue (Wong 1976). The Bahamians make a medicine for tuberculosis with prickly pear (*Opuntia*) and wood ashes (Eldridge 1975). The grass is also medicinal in Belize (Balick et al. 2000).

### ***Passiflora*: Passion-Flower**

(Linnaeus reversed the Latin *Flos passionis*; crucifixion flower, originally used by Nicolas Monardes)

Virtually every discussion about passion-flowers tells of the comparison between the passion of the crucifixion of Christ and the flowers. Jesuit priests made that analogy in their efforts to convert the New World people. Presumably, the “*leaf*” symbolizes the spear. The five *petals* and five *sepals* the ten apostles (Peter who denied, and Judas who betrayed, being omitted). The five anthers, the five wounds. The *tendrils*, the scourges. The *column* on the ovary, the pillar of the cross. The *stamens*, the hammers. The three *stigmas*, the three nails. The *filaments* within

*Passiflora suberosa*. Drawn by  
P.N.Honychurch.

the flower, the crown of thorns. The *calyx*, the glory or nimbus. The *white* tint, purity. The *blue* tint, HEAVEN” (Coffey 1993). What most accounts do not add is the historical sequence behind that story.

Nicolas Monardes was perhaps the first to use the Latin term *Flos passionis* (flower of the crucifixion) in 1582. Since that story and the plant were not part of John Frampton’s ([1577] 1925) translation, Englishspeaking people were rarely aware of Monardes’s role. Supposedly, the same species was brought to Europe by Jac Boccio in 1610, and that introduction may have been the source of cultivated plants in England, Holland, and Sweden (Svanidze et al. 1974).

The same passion-flower, later named *P. incarnata*, was mentioned by Strachey ([1612] 1953) on the James River of Virginia: “Here is a Fruict by the Naturalls called a *Maracock* this groweth generally lowe and creepeth in a manner amongst the Corne...yt is of the bignes of a Queene-apple, and hath many azurine or blew kernells, like as a Pomegranett, and it bloometh a most ssweet and delicate flower, and yt is a good Sommer Cooling fruit, and in every field where the indigenous people plant their Corne be Cart-loades of them.” His original notes on the Powhatan used *maracah* (Harrington 1955). That same year Capt. John Smith reported that the indigenous people planted “*Maracocks*, a wild fruit like a lemmon, which also increase in fruit” (Coffey 1993). Subsequently, herbalist Caspar Bauhin recorded the species in 1623. Parkinson ([1629] 1976) wrote that the plant “Maybe called in Latine, *Clematis Virginiana*; in English, the Virgin or Virginia Climer; of the Virginians, *Maracoc*; of the Spanish in the West Indies, *Granadillo*, because the fruit...is in some fashion like a small Pomegranate on the outside.”

However, it was the name *Granadilla hispanis*, *flos passionis italica* (little Spanish pomegranate, Italian passion flower) published by Francisco Hernández in his book of 1651 that was the earliest firsthand record Linnaeus had as the basis for *Passiflora* in 1753. Not only did Linnaeus have the description and drawing from Hernández, but he also knew that the plants had been cultivated in England from the 1600s. Indeed, Linnaeus had studied the live plants at the *Hortus Cliffortianus* (Holland) and *Hortus Uppsaliensis* (Sweden). All these names had been applied to the species that Linnaeus

called *P. incarnata* (flesh-colored). He was mistaken about the flower color because they are blue.

The Latin *Flos passionis* became *flor de la pasión* (Spanish), *fleur de la passion* (French), *flor da paixão* (Portuguese), and passion-flower as generic equivalents of the genus *Passiflora*. The apparent lone exception to these names is in Puerto Rico where the genus is called *parcha* (from *palcha*, Quechua). Today *parcha* is mostly associated with the introduced South American *P. edulis*. Probably the plant and its name were introduced at the same time from Peru where now *P. edulis* is called *maracuya*.

The names *maricock* and *maracocks* gave rise to maracoc, maycock, maypop (Alabama, North Carolina), mayapple (Alabama, North Carolina), Mollypop (Alabama, North Carolina), pop-apple (North Carolina), apricot (North Carolina), and apricot-vine (Texas). All of these names are supposedly derived from *mahcawq* [mäkak, mä'kâwk] (Powhatan), akin to *machkak* (Menomini), *mākāk* (Cree, Ojibwa), and *ma'ka'kwi* (Fox). Although similar, there seems to be no relation to Tupí *mboruku'ya* or *marau'yá*, in Portuguese *maracujá*, and *maracuya* in Spanish, names for *P. edulis* (Gerard 1907).

*Passiflora incarnata* is also known as *granadilla* (little pomegranate, Texas, Florida fide Williams [1837] 1962), Holy-Trinity flower (Texas), *pasionaria* (of the crucifixion, Texas), passion-vine (North Carolina), and purple passionflower (Florida). *Opako* is the Alabama name, and it is almost identical to the Koasati *apakó*, Muskogee *opvkv* [opv'kv], and Miccosukee *opakī*. Probably belonging here is *lānansi* (*laana*, yellow, *osi*, suffix meaning extremely, Alabama). The plant designated by the Alabama name is described as having a "small sweet melon, smells like a honeydew, makes the mouth itchy, size of an orange; a vine with a fruit similar to passion fruit (if one eats too much of it, it will blister the tongue and mouth)" (Sylestine et al. 1993). The species ranges from Virginia to Missouri, south to Florida and Texas and Bermuda, and it is introduced farther north in the United States.

In addition to eating the fresh fruits (*uwa'ga*), the Cherokee made a social drink of them, mixing the juice with cornmeal as a thickener. That would be a drink akin to *horchata* in Latin America. Most surprising is that the Cherokee also parboiled and then fried the leaves in hot grease as a potherb (Hamel and Chiltoskey 1975).

The Cherokee and other indigenous people used *P. incarnata* as medicine. A compound infusion of the roots was used to treat boils, and roots were used to stop inflammation of wounds. Infants were given infusions of the roots to aid in weaning, and it also was used to relieve earache (Hamel and Chiltoskey 1975). The Houma called it *chassepareille incarnata* (flesh-colored saw brier), and took an infusion of the roots as a blood tonic (Speck 1941). Whole plants have traditionally been used in a tea as an antispasmodic and as a sedative for neuralgia, epilepsy, restlessness, painful menses, insomnia, and tension headaches.

Linnaeus ([1753] 1957) also published the Florida species *P. lutea* (yellow passionflower, Florida), *P. multiflora* (whiteflower passionflower, Florida; *fruta de perro*, dog fruit, Cuba; *pasionaria vainilla*, vanilla of the crucifixion, Cuba), and *P. pallens* (pineland passionflower, Florida). Similarly, Linnaeus named *P. sexflora* and *P. suberosa*, which are better known within the Caribbean.

*Passiflora sexflora* grows in Florida, the Greater Antilles to Puerto Rico, and from Mexico to Panama and Colombia. In those areas the plant is known as *ala de murciélago* or bat wing (Jamaica), duck foot (Jamaica), duppy pumpkin (Jamaica), goat foot

(Jamaica, Florida), and *pasionaria de cerca* (fence passion vine, Cuba). Guatemalans make a sedative preparation of the flowers for nerves, insomnia, and diarrhea.

Even more noted is *P. suberosa*, native from southern Florida to southern Texas to northern South America and the West Indies, introduced into the Old World. That species like all the others has edible fruits, although they are smaller than most. The edible fruits gave rise to the names *baleeyml an 'its'aamal* (deer watermelon, Huastec, San Luis Potosí), *huevo de gallo* (rooster egg, Cuba), juniper berry (Bahamas), *meloncillo* (little melon, Cuba), *morita* (blackberry, Dominican Republic), *parcha yedra* (ivy passionfruit, Puerto Rico), *parchita de culebra* (snake's little passion-fruit, Venezuela), and wild pumpkin (Caymans). Fruits are also used to make black ink as noted by the names indigo berry (Virgin Islands), ink berry (Virgin Islands), and ink vine (Barbados).

There are always names that are at odds with others. *Passiflora suberosa* is called corky passionflower in Florida because some scholar simply translated the Latin name. In Yucatán, the Maya say *kansel-ak* (*kants'il*, like cotton, *ak*, vine). Supposedly, it is called that because it is covered with trichomes like cotton, but most Florida plants are glabrous. In Hispaniola it is *leontafia* (lion's *aguardiente* or whiskey) or *tidiane* (little Diane).

When I first experienced juice from *maracujá* in Belém, Brazil in 1969, I was told that it was good to drink with dinner because it aided digestion and calmed the nerves. At the time, I drank it because it tasted good, but I could not really notice the effects.

Subsequently, I discovered that several species are considered calmants or even intoxicants (Fellows and Smith 1938, Speroni and Minghetti. 1988, Medina et al. 1990, Solbakken et al. 1997, Dhawan et al. 2001a,b,c). Some experiments support the tranquilizing conclusion, while others do not (Coleta et al. 2001, Volz 2001). One other caveat is that the commercial extract is possibly toxic, at least in some individuals (Fisher et al. 2000). However, most results indicate that plant extracts are mildly sedative, reduce blood pressure slightly, and decrease motor activity.

In addition to the supposed sedative effects of *Passiflora*, several others are known, including as an adjuvant agent in the management of opiate withdrawal, and as an antibacterial, anticonvulsant, anti-fungal, and antioxidant (Nicolls et al. 1973, Medina et al. 1990, Akhondzadeh et al. 2001, Murcia et al. 2001, Taglioli et al. 2001). Perhaps the most surprising result was in neutralization of hemorrhage from the fer-de-lance (*Bothrops atrox*) venom (Otero et al. 2000), although bleeding decreased only 25%.

Chemicals have been identified from several species, including *P. edulis*, *P. foetida*, *P. incarnata*, and *P. quadrangularis*. Compounds found are the alkaloid passiflorine, benzylic beta-D-allopyranosides 1 and 2, which are representatives of a rare class of natural glycosides, flavonoids, cycloartane triterpenoids and six related saponins, harmaline and harmine, oxygenated monoterpenoids, and passifloricins (polyketides alpha-pyrone) (Lutowski and Wroczynski 1960, Bennati 1971, Morton 1981, Osorio et al. 2000, Yoshikawa et al. 2000a,b, Christensen and Jaroszewski 2001, Echeverri et al. 2001). Harmaline and harmine have been used to treat Parkinson's disease (Swerdlow 2000).

In the 1960s, it was uncommon to find passionfruit juice in groceries, even in mixtures. Then a television commercial made "passion-fruit" an everyday word because it was an ingredient (minor) in "Hawaiian punch." The ad showed one cartoon character "punching" another when they said they wanted the drink. Everyone laughed at the catchy phrase, although few realized what a passion-fruit was. Botanists knew it was *Passiflora*, and somehow we felt smug knowing that bit of trivia.

### *Pavonia*

(Antonio José Cavanilles named this for José Antonio Pavón y Jimenez, 1754–1844, a Spanish explorer who toured Chile and Peru with Hipolito Ruiz López and Joseph Dombey)

- Pavonia paludicola*** (swamp-loving) (= *R. spicata*)
- cadillo de ciénaga* (marsh sticker, Puerto Rico)
- cotton (Belize); wild cotton (Belize)
- gombo-mangle* (mangrove okra, Guadeloupe, Martinique)
- kayuwaballi* (*kayuwa*, mahoe or *Hibiscus tiliaceus*, *balli*, resembling, Arawak, Suriname)
- mahot mangle [mare]* (mangrove [ocean] fiber tree, Taino and French, Guadeloupe, Martinique); *mahuat* (fiber tree, Taino, French Antilles); *majagüilla* (little fiber tree, Hispanized Taino, Cuba, Hispaniola); smaller mahoe (Jamaica)
- mangrove mallow (Guadeloupe, Martinique)
- sunabao* (Guadeloupe, Martinique)
- swamp bush (Bahamas, Puerto Rico)

*Pavonia* was created in 1786 by the director of the botanical garden in Madrid, Cavanilles (1745–1804). However, it was not until 1989 that Dan Nicolson and Paul Fryxell described *P. paludicola* from the Lesser Antilles. That species brought the genus to a total of 150 species found in tropical and warm regions of the world (Mabberley 1997).

In the French Antilles, the leaves are applied to inflammations, boils, and abscesses (Morton 1981). In Haiti, an infusion is gargled for tonsillitis. Taken regularly, it is laxative.

### *Pectis*

(From Latin *pecten*, *pectinis*, a comb, referring to the bristles along the margins of the leaves or the papus)

- Pectis prostmta*** (lying flat)
- cominillo [tomillo]* (little dwarf, Venezuela); *comino de piedra [de sabana, rústico]* (stone [savanna, wild] dwarf, Venezuela)
- contra-yerba* (herb against, typically meaning that it can be used to treat any malady)
- hierba de gallina* (chicken herb); *hierba de chinche* (bedbug herb)
- romero macho* (wild [male] rosemary, Puerto Rico)
- tebenque [tebenki, tebink, theebink]* (probably Taino, Cuba); *tebink moge* (probably Taino, Cuba?)
- zacato-coche* (car grass; probably because it is common on roadsides)

*Pectis prostrata* has been reported from a number of places in the Caribbean, but there are indications that those are misidentifications. For example, the *Flora of Cuba* reported the plants from Jamaica, but Adams (1972) could not verify that they had ever been there. Similarly, Morton (1981) recorded medical use in Puerto Rico, but Liogier and Martorell (1982) do not include the species. TROPICOS lists specimens from Texas, Mexico (Chiapas, Tabasco, Yucatan), Belize, Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, Panama, and Ecuador.

Maybe the true distribution is less important for ethnobotanical comments because people often do not distinguish species. In Venezuela, for example, both *P. ciliaris* and *P. prostrata* have the same names (Pittier 1926). Perhaps that is because the aromatic traits of both are similar.

*Pectis prostrata* has been taken to stop diarrhea, dispel flatulence, as an emmenagogue, and for venereal diseases in Venezuela (Pittier 1926). In Jamaica and Puerto Rico, it is taken for colds and tuberculosis (Morton 1981). The species is used as a medicine in Belize (Balick et al. 2000). Hocking (1997) reported that it had been used to treat colds and tuberculosis, to expel flatulence, and as an emmenagogue.

### *Pedicularis*

(Named from Latin *pediculus*, a louse, because Europeans believed that cattle or sheep feeding where *P. palustris* grew became covered with lice; also *herba pedicularis*, lousewort, because it was used to kill lice)

*kallgrås* (*kail*, cold?, *grås*, grass, Swedish)

*Läusekraut* (louse herb, German)

*myrklegg* (*myr*, bog, *klegg*, gadfly, Norwegian)

*pédiculaire* (French); *pediculare* (Italian)

*riabhach* (gray or grizzled, Gaelic)

### *Pedicularis canadensis* (of Canada)

beefsteak-plant (Long Island)

betony [betong, beton lousewort, head-betony] (“betony,” from Latin *betonica*, which Pliny, A.D. 23–79, said was a Gaulish name; *betonica*, from *vettonica*, derived from Vettones, people of Lusitania, originally applied to *Stachys officinalis*, New York); wood-betony (“wood” meaning growing wild, as opposed to the cultivated betony, *Stachys officinalis*)

*cagacka'ndawesoanuk* (flying squirrel tail, Potawatomi)

chickens'-heads (Long Island)

***Pedicularis canadensis*.** a. Habit, b. Flower, c. Stamen, d. Pistil, e. Fruit.

*Drawn by Vivian Frazier. From Correll and Correll 1972.*

[Canadian, common, early, early fern-leaf] lousewort (“louse” from a Teutonic base-word, as Old English *lūs*, with cognates in German *Laus*, Danish and Swedish *lus*; first applied to *Helleborus* in the 1540s by Leonard Fuchs, as *Laüszkraut*, and later to *Pedicularis* by John Gerarde in 1597); lousewort-foxtail

snuffles (presumably from “snuffles” or “sniffles,” a nasal catarrh, used since the 1820s; a local name in England, usually applied to *Rhinanthus*, also in the Orobanchaceae, formerly Scrophulariaceae; cf. Coffey 1993)

Linnaeus included Sweden’s *Pedicularis* in his *Flora Oeconomica* of [1749] 1979. When he published *Species Plantarum* in 1753, all of its 14 species were Old World plants. It was not until 1767 when Linnaeus published *Mantissa Plantarum* that he gave us *P. canadensis*, based on a collection by his student Peter Kalm in Canada.

People of the northeastern United States had known about this *Pedicularis* and other species for a long time by the 1760s. About 1750, Jane Colden wrote concerning what is now *P. canadensis*: “This pedicularis is call’d by the country people Betony. They make

a Thee [tea] of the leaves, et use it for the fever & ague et for sickness of the stomach” (Colden in Coffey 1993). Settlers may have known about medicines from Old World species, or they may have learned from the indigenous tribes.

Moerman (1998) recorded use among eight tribes. The Catawba made an infusion of roots to treat stomach problems. The Cherokee treated dysentery, coughs, and stomachaches with it (Hamel and Chiltoskey 1975). They and the Iroquois also rubbed an infusion of roots on sores. The Iroquois treated women’s menstrual problems, heart troubles, and bleeding tuberculosis with the plants. The Menomini used it as a love charm. The Meskwaki treated external sores and tumors, and also made a love medicine with it (King 1984). The Mohegans used an infusion of leaves to induce abortion. The Ojibwa used a root infusion to counteract anemia, to treat stomach ulcers, sore throats, and as a love potion. The Forest Potawatomi used the roots as a physic, while the Prairie Potawatomi used the roots to reduce both internal and external swelling (Smith 1933).

The Menomini and Potawatomi mixed lousewort with other plants to fatten their horses. Both the Cherokee and Iroquois ate the leaves and stems, sometimes cooking and seasoning them with salt, pepper, and butter (Yanovsky 1936).

In the 1750s some Europeans still believed that cattle or sheep feeding where *P. palustris* grew became covered with lice. By the 1900s, others had totally changed views. Vickery (1993) recorded that people in the Shetland Islands called *P. vulgaris* “bee-sookies” or “honey-sookies” because of its “nectar-filled flower-tubes,” which children sucked for their sweet flavor.

### *Pediomelum*

(Per Axel Rydberg, 1860–1931, segregated these plants from *Psoralea* with Greek *pedion*, field, and *melon*, an apple or fruit)

***Pediomelum canescens*** (grayish-pubescent) (= *Psoralea canescens*)  
buck-horn [buck-thorn] (“buck-thorn” is now applied to several genera, but was applied to *Rhamnus catharticus* by Dodoens in 1554; the Latin *cervi spina* was applied to *Rhamnus* by Valerius Cordus, 1514?–1544)

buckroot (known by this name in 1765 when John Bartram visited the Carolinas, Berkeley and Berkeley 1982)

hoary scurfpea (“scurf” is dry, scaly skin, especially on the head; probably from Old English *scurf*; akin to Swedish *skorv*, Danish *skurv*, Dutch *schurft*, and German *Schorf*)

*owá:lá:rí: insawá:kí* (Sturtevant wrote “prophets” [plural; singular, *owá:lí*] coconut,” Mikasuki; “*owá:lí*” is also translated as “wise-man,” “magician,” or in Creek, as “knower”); *owa:lálki insawkô* (*owaly*, knower, *em*, his, *svokv*, rattle, Creek; the “coconut,” *Cocos nucifera*, is *talasvokv*)

These herbs are restricted to parts of Virginia, Georgia, Florida, and Alabama (Radford et al. 1968). Because of their limited range, not much has been written about them, yet the Seminoles knew and used them as late as the 1950s (Sturtevant 1955). Moreover, they

were familiar with the restricted range of the plants in Florida, noting that they did not grow south of Punta Gorda. They would make special trips into the area where the plants grew to obtain stocks of the roots to dry for use in medicine. Hedrick (1919) and Yanovsky (1936) say the roots have been eaten in the southern states.

According to Josie Billie, one of Sturtevant's collaborators, these legumes were analgesic when the warmed root was applied externally. To treat rheumatism, they took a root, dipped it in water, warmed it over the fire, and then pressed it against the sore spots. They considered it strong and expected the pain to be gone by the next morning. In addition, the roots were used in a medicine to treat colds and coughs. Sturtevant (1955) gave a lengthy account of his personal experience treating his own cold, and he was convinced it helped.

Neither Foster and Duke (1990) nor Duke (2002) even mention the genus *Pedimelum*. Under *Psoralea*, Hocking (1997) says that this species has been used to treat gastric distress.

### *Peltandra*

(Rafinesque named this with Greek *pelte*, a shield and *andros*, stamens)

***Peltandra virginica*** (from Virginia)

[green] arrow [arum] (USA)

*ocfô* (Creek); *okô:nî* (Mikasuki)

***Peltandra virginica*.** a. Habit, b. Outline of leaf. c. Spadix. d. Berry (submersed). Drawn by Vivian Frazier. From Correll and Correll 1972.

*Pfeilaronstab* (arrow arum stick, German)

*takwahahk* (Capt. John Smith wrote the Powhatan name as *tockwhogh*, *tocknough*, and *tockawhough*. He said that it was the “chief root they have for food...like a flag in low muddy freshes...of the greatness and taste of potatoes ...raw it is not better than poison...roasted... in summer they use this ordinarily for bread.” Strachey wrote in [1612] 1953 that it was a “bread made of a wort called *taccaoappoans*” Siebert 1975 considered the root to be /\**takw*-, to pound fine, beat to a powder. The word written by Strachey includes the element *appoans*, which became “pone” in English; see also *Zea*); cognates include *takáham* (Delaware); *takwaham* (Cree); *takwahamwa* (Miami); *takwham* (Nipmuck-Pocumtuck); *taw-ho* [*tawho*, *tawhim*, *tawhim*, *tuckah*] (Delaware, New Jersey); *tquogh* (Mohegan); *tukwhah* (Shawnee); *nitakhwa* (“I pound him for bread,” Shawnee); *otakwa?an* (Ojibwa)

*tuckahaw* (according to Romans [1775] 1961, there was a Chickasaw town named for this plant, and using the Algonquian word)

*tuckahoe* [*tockwhogh*, *tockawhough*, *taw-ho*] (from Powhatan, Virginia); *coscúshaw* (Carolina Algonquians; see also Geary 1955)

[Virginian] wake robin (New England)

Although there is considerable confusion about the original identify of *tuckahoe*, it has become associated with *Peltandra* since being discussed by Kalm ([1753–1761] 1972), who had personal knowledge of the plants and the people using the name. That Powhatan word is related to *petukqunneg* (cake of bread, from *petukqui*, bread, *pitikwah*, made round, Cree). The distribution of the words presumably corresponds to part of the range of usage. However, most of these terms were transferred to maize when it was introduced, and that has complicated the situation.

The first record of the indigenous use of these roots is in 1612 when Capt. John Smith wrote, “In lune, lulie and August they feede vpon the rootes of *Tockwough*, berries, fish and green wheat [maize]” (OED 1971). Strachey recorded the plant and name the same year. The Seminoles also use the plant for food (Sturtevant 1955). Tull (1999) indicated that long periods of drying (sometimes months) and baking are necessary to render the acrid roots palatable. Both roots and fruits were eaten after detoxification. Methods of preparing them are given by Fernald et al. (1958).

Harriot ([1590] 1972) had recorded another name and use among his list of fruits. He called them *sacqvenvmnener*, and not long afterward Strachey and Capt. John Smith called them *ocoughtanamins*. Harriot ([1590] 1972) wrote that *sacqvenvmnener* were “a kinde of berries almost like vnto capres [capers, *Capparis*] but somewhat greater which being grow together in clusters vpon a plant or herb that is found in shallow waters: being boiled eight or nine hours according to their kind are very good meate and wholesome, otherwise if they be eaten they will make a man for the time franticke or extremely sicke.” Smith thought they should be boiled half a day (Swanton 1946).

Yanovsky (1936) may have confused *Orontium* with *Peltandra*. Still, he listed *Peltandra* as having been eaten in all the southeastern states, and in New York, Pennsylvania, and Virginia, a distribution agreeing with its Algonquian names.

Moerman (1998) indicates that the Nanticoke of Delaware grated the roots in milk and gave it to babies for some unstated medical reason.

### *Penstemon*

(From Greek *pente*, five, and *stemon*, stamen, referring to the four fertile stamens and one sterile staminode)

#### *Penstemon laevigatus* (smooth)

[eastern smooth, foxglove, hairy] beard-tongue

Europeans were familiar with *Digitalis* when they arrived in the New World, but here they found plants somewhat different from that old medicinal herb. When Casimir Christoph Schmelde (1718–1792), a German physician at Erlangen, was working with plants grown in Kew Gardens outside London, he decided that the American plants should have a distinct name. He called them *Penstemon* in 1763 because of their androecial arrangement. The genus now has grown to 250 species, with all but one confined to North America (Mabberley 1997).

One of the species discovered after Schmelde was *P. laevigatus*. This herb, also described from plants grown at Kew, was named by William Aiton in 1789, and the specimen he used to name the species is in the Fothergill collection at the British Museum of Natural History. Smooth beard-tongue ranges from New Jersey, Pennsylvania, and West Virginia south to Florida (Gadsden and Jackson Counties), and west into Alabama and Mississippi.

Not much information is available about this plant. The Cherokee used an infusion of *P. laevigatus* to stop cramps (Hamel and Chilton 1975). This is probably the same species used by the Creeks and Natchez for colds, coughs, consumption, and whooping cough (Swanton 1928a).

Porcher (1863), Millspaugh (1892), Vogel (1970), and Foster and Duke (1990) do not mention the genus. However, other *Penstemon* species were used by the Iroquois, Kiowa, Lakota, Pawnee, and several tribes farther west. Moerman (1998) found records of 23 other species being used.

Some *Penstemon* contain iridoid glycosides, especially catapol, and both moths and butterflies have adapted to sequester and use those compounds. The inchworm and looper moths *Neoterpes graefaria* and *Meris alticola* take catapol from *Penstemon*, and the Arachne checkerspot butterfly (*Polydryas arachne*) also uses it.

### *Pentalinon*

(Friedrich S. Voigt, 1781–1850, named this with Greek *pente*, five, and *linon*, rope, a reference to the elongated anther appendages)

***Pentalinon luteum*.** a. Flowering branch, b. Node. c. Flower tube, longitudinally dissected, d. Floral diagram, e. Fruits, f. Seed with coma. g. Seed. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

- Pentalinon luteum*** (yellow) (= *Urechites lutea*)  
 [bejuco] ahoga vaca (cow strangler [vine], Dominican Republic)  
 barbeiro amarillo (yellow beard, Puerto Rico)  
 bejuco marrullero (false? climber, Cuba)  
 Catesby's vine (Bahamas)  
 clavelitos (little carnation, Cuba)  
 corne cabrits (goat horn, Haiti)  
 curamagüey (Taino?, Hispaniola)  
 Dominican viper tail (Dominican Republic); hammock viper's tail  
 [viperstail] (Florida)  
 Jamaica nightshade (Jamaica); yellow nightshade (Jamaica?);  
 nightshade (Cayman Islands)  
 wild allamanda (Florida)  
 wild unction (unction=ointment, Bahamas)

Linnaeus ([1753] 1957) called these climbers *Vinca lutea*. Then, for many decades, they were called *Urechites lutea*, a genus established in 1860 by the Swiss botanist Johannes Müller of Aargau. However, Bruce Hansen realized that *Pentalinon*, described from plants grown in the Calcutta Botanical Garden in 1845, was an earlier and valid generic name (Hansen and Wunderlin 1986). *Pentalinon* now contains two species, both native to Florida, Central America, and the Caribbean.

In the Dominican Republic *Pentalinon* is used to treat heart disease (cardiotonic), edema, fever, and colic, and as a purgative (Hocking 1997). Plants are used to treat headache in Guatemala (Rosatti 1989). However, doing so is dangerous because the latex is poisonous, having been used to poison arrows in tropical countries (Rosatti 1989). It is poisonous to cattle; people powder the leaves to kill destructive insects and animals (ants, dogs) (Liogier 1974). Among the poisonous compounds are the cardenolides oleandrin, urechitin, and urechitoxin (Gibbs 1974).

### *Penthorum*

(From Greek *pente*, five, and *hows*, a column or pillar, referring to the five-parted flowers)

***Penthorum sedoides*.** a. Top of plant, b. Part of procumbent stem of plant with roots, c. Cluster of flowers and fruits. Drawn by Vivian Frazier. From Correll and Correll 1972.

***Penthorum sedoides* (like *Sedum*)**

[ditch, Virginia] stonecrop (from Old English *stāncrop*, combining “stone,” a rock, and “crop,” as gathered from the top of an herb for culinary or medical purposes; combined, the designator has been in use since about A.D. 1000, first as the common name for European *Sedum acre*; modifiers were added later for other plants)

*Penthorum* has been an oddity since it was discovered. Jan Gronovius first included it in his *Flora Virginica* of 1739–1743. Linnaeus described it in 1744, and in *Species Plantarum* ([1753] 1957) said only of it that it had a “Habitat in Virginia.”

Depending on how it is interpreted, the single American species either belongs in the Saxifragaceae along with one to three others that grow in Asia, or in its own isolated family, the Penthoraceae (Cronquist 1981, Mabberley 1997). In some regards, the plants are transitional between the Saxifragaceae and Crassulaceae (Cronquist 1981).

*Penthorum sedoides* grows from New Brunswick, southwestern Quebec, southern Ontario, Michigan, Wisconsin, Minnesota, and Nebraska south to Florida and Texas. Within that large range, only two tribes have been recorded as using the plants.

In her 1975 master’s thesis at the University of Tennessee, Knoxville, Myra Jean Perry recorded that the Cherokee used the leaves as a potherb (Moerman 1998). That is an odd use, indeed, because few to none of the other members of the family are considered edible. In Iowa, the Meskwaki made a cough syrup of the seeds (King 1984).

Although the plants are not mentioned by Porcher (1863), they are discussed by Millspaugh (1892). He wrote, “It has always held a place in domestic practice as an astringent in diarrhoea and dysentery.” According to him, two physicians brought the plants to notice in 1875 as a remedy for irritation of the mucous membranes and to treat maladies like pharyngitis, vaginitis, and tonsillitis. In 1931, Maud Grieve’s book *A Modern Herbal* included the report that “this plant has of late attracted much notice...as a remedy for catarrh, catarrhal inflammation of the larynx, chronic bronchitis...and affections of the stomach and bowels. It has also been employed with success in treatment of diarrhoea, haemorrhoids and infantile cholera” (Coffey 1993). Foster and Duke (1990) echo the same information, but the species is not mentioned by Bremness (1994), Bown (1995), or Duke et al. (2002).

***Peperomia***

(Ruíz and Pavón combined Greek *peperi*, pepper, and *homoimos*, resembling)

***Peperomia obtusifolia*** (leaves blunt or round at apex)

*agronemia* (of cultivated places?, Hispaniola)

climbing pepper (Belize); wild pepper (Florida, Bahamas)

*cupeycito* (little cupey, *Clusia rosea*; Hispanized Taino, Dominican Republic)

*lentejuela* (applied to *Lepidium virginicum* in Morton 1981)

*pàrahá* (Paya, Honduras)

peperomia (Florida)

*tep-pim* (*tep*, something adorned, *pirn*, fat or large, Maya, Belize)

The genus *Piper* was the only one that Linnaeus ([1753] 1957) recognized, and he included 17 species. He called these plants *Piper obtusifolium*, and noted that they had been discussed previously by Charles Plumier in 1693 as *Saururus repens*, *folio orbiculari nummulariae facie* (prostrate lizard's tail, with rounded leaves resembling coins). Then, after their exploration of Peru, Hipólito Ruiz López (1754–1815) and José Antonio Pavon (1754–1844) created the genus *Peperomia* in 1794 in their book *Flora Peruviana, et Chilensis Prodromus* (Preliminary Flora of Peru and Chile). The genus now contains 1000 tropical species, mostly in Americas (Mabberley 1997).

Several of the *Peperomia* are widely used as medicines. *Peperomia pellucida* is the most famous (Liogier 1974, Ayensu 1981, Morton 1981), but *R magnifoliifolia* is more similar morphologically to *P. obtusifolia*, it has even been recorded in botanical literature under the latter name. *Peperomia magnifoliifolia* is used in Barbados as a remedy for coughs and colds (Morton 1981). In Veracruz, the Zoque-Popoluca treat erysipelas with it (Vásquez and Jácome 1997).

### ***Persea*: Red Bay**

(A classical name doubtfully from *Persica*; from Persian, or from Greek *persis*)

Americans and Bahamians call *Persea borbonia* the red bay. They have used that name since at least the time of Mark Catesby (1731). Calling trees “bays” is obvious because they belong to the same family of plants (Lauraceae) called by that name since the time of the Greeks and Romans. “Bay” is derived from Latin *baca*.

Until recently, it never occurred to me to ask why the plants were called “red” bays. When a colleague asked me why, I found that “red” in the name refers to the wood. Of the trees that he saw in Virginia and

***Persea borbonia*.** a. Branch with flowers, b. Bud. c. Flower, d. Anther, e. Branch with fruit. *Drawn by Vivian Frazier.* From Correll and Correll 1972.

Carolina, Catesby said, "The wood is fine-grain'ed, and of excellent use for Cabinets, etc. I have seen some of the best of this Wood selected, that has resembled Water'd Sattin, and has exceeded in Beauty any other Kind of Wood I ever saw." Sargent (1905) wrote that the wood was "heavy, hard, very strong, rather brittle, close-grained, bright red." The wood has been used from at least the time of Catesby for cabinets, and also on the interior finish of houses. Formerly, it was used in ship- and boatbuilding. Comparing its wood to mahogany with "Florida mahogany" is high praise indeed.

Williams ([1837] 1962) also praised the wood. He wrote, "This tree produces timber inferior only to mahogany, which it closely resembles." He then added, "The young leaves are often used for tea, which is a most pleasant and healthful beverage."

The Flemish Charles de l'Ecluse, who became the king's botanist to James I of England, was the first to apply the name *Persea* to these plants. Philip Miller picked up the name and continued its use. That Greek name originally was used by Theophrastus and Hippocrates for an unknown Egyptian tree. Of that tree, Pliny wrote, "*Persea*...is far different from the Peach-tree *Persica* and beareth fruit like unto Sebes ten, of colour red" (from a 1602 translation). The derivation of *Persea* was thought by Pliny to be the same as *Persica* (from Persia), but that is dubious. Apparently, Persia is derived from Greek *persis*, which in turn was probably taken from Arabic *fars*. Some have speculated that the

Old World plants called *Persea* were *Cordia myxa* (Boraginaceae), but their identity remains uncertain.

Curiously, Linnaeus did not follow either l'Ecluse (alias Clusius) from 1601 or Gaspar Bauhin from 1623 in keeping these plants distinct from *Laurus*. Instead, Linnaeus called the plants *Laurus persea*, which we now know as *P. americana* (avocado). Linnaeus's reluctance to keep *Laurus* separate from *Persea* is reflected today in the chaotic status of genera in the family.

Other names for red bay and its variations (including *P. pubescens*) are laurel-tree, shore bay, swamp bay, swamp red-bay, sweet-bay, and tiss-wood. The last name, "tiss-wood," may be related to its use in tisanes for a beverage or medicine. The first record of it that I saw was by Vignoles ([1823] 1977) who spelled it "tiswood." Almost certainly, this plant and sassafras (*Sassafras albidum*) have been used interchangeably since Europeans encountered people using them. Leaves of both have served as the basis of gumbos (from Choctaw, *kumbo*), especially those including crabmeat.

The Miccosukee call these trees *tó:lí*, their relatives the Creeks say *tó: la*, and the Koasati say *tolá*. Surprisingly, because they were supposed to have a distinct language, the Timucua also said *tola*. Those are simple terms that cannot be translated. However, the Alabama call the tree *ittoissi kosáoma* (*itto*, tree, *hissi*, hair, *kosooma*, stinking). This may be what the Choctaw called *iti chinisa* (striped tree).

William Bartram ([1791] 1958) recorded that the trees were called *eto mico* [*itto micco*, *eto micco*] (*eto*, tree, *mekko*, tree, Creek). Simmons ([1822] 1973) noted that the Seminoles were still using the name. This tree is perhaps the most important plant among modern and historic Seminoles. The Seminoles used the leaves to make a beverage like tea. They also used the dried leaves in cooking like their relatives the Choctaw, and they made spoons from the wood. They were not the first to use the plants in Florida, as the pollen of *P. borbonia* has been found in a pre-Columbian site near Lake Okeechobee (Hogan 1978).

Red bay has been used by the Seminoles as an abortifacient, analgesic, antiemetic, diuretic, aphrodisiac, emetic, febrifuge, a laxative, a love medicine, a panacea, a psychological aid, in childbirth, to cure dreams, and to improve the appetite, as well as in a ceremonial context (Sturtevant 1955). The Creeks and their relatives the Seminoles diagnose diseases in ways different from Europeans and Americans. Each series of symptoms is identified with a name as in our system, but their nomenclature involves an animistic worldview. Among the diseases they recognize, *Persea* has been used to treat "Bear Sickness" (fever, headache, thirst, constipation, and blocked urination), "Bird Sickness" (diarrhea, vomiting, appetite loss), "Buzzard Sickness" (vomiting in children), "Cat Sickness" (nausea), "Dead People's Sickness" (grief, cough, appetite loss, vomiting; sometimes the same as "Ghost Sickness"), "Deer Sickness" (numb, painful limbs and joints), "Fire Sickness" (fever and body aches), "Ghost Sickness" (grief, cough, appetite loss, vomiting, dizziness, staggering, sometimes the same as "Dead People's Sickness"), "Hog Sickness" (unconsciousness), "Mist Sickness" (eye disease, fever, chills), "Opossum Sickness" (appetite loss and drooling in babies), "Otter Sickness" (diarrhea and vomiting), "Raccoon Sickness" (diarrhea in babies), "Rainbow Sickness" (fever, stiff neck, backache), "Scalping Sickness" (severe headache, backache, low fever), "Sun Sickness" (eye disease, headache, high fever, diarrhea), "Thunder Sickness" (fever,

dizziness, headache, diarrhea), “Turkey Sickness” (dizziness or “craziness”), and “Wolf Sickness” (vomiting, stomach pain, diarrhea).

Additionally, red bay has been used to treat sickness caused by adultery, including headache, body pains, and “crossed fingers.” As an aphrodisiac, the leaves are sung over to attain the love of a particular girl. If the aphrodisiac has worked, the leaves may be rubbed on the mother’s body during protracted labor.

Sometimes red bay is even considered a panacea where the leaves are used for everything and can be added to any medicine. As a psychological aid, the leaves are used to cure fear in babies caused by dreams about raccoons or opossums. In addition, an infusion of leaves may be used to steam and bathe the body of an “insane” person. The plant may be burned to work the same cure.

There are also particular ceremonial applications. A decoction is taken as an emetic by doctors to strengthen their medicine. That may be the use at any time, or particularly when a death has occurred. The leaves are used as emetics during funeral ceremonies, carried by every member of the burial party, placed on top of casket, and burned to keep the soul of the recently departed from returning home. Leaves are also added to food after a recent death.

Some recognize a wetland form as a distinct species, calling it *P. palustris*. The Creeks have used the root of that form as a “hydrogogue” and alterant. The decoction is considered diaphoretic in “fevers of all descriptions” by the Choctaws (Bushnell 1909).

*Persea* is notorious for having poisonous compounds although it provides food and medicine for humans and other animals. The red bay and its variations contain an array of essential oils, including camphor, cineol, eucalyptol, and p-cymene (Tucker et al. 1997). Those, and probably other chemicals yet to be identified, are responsible for the tight evolutionary relationship between the spicebush swallowtail butterflies and members of the Lauraceae. The spicebush swallowtail (*Papilio troilus*) and the Palamedes swallowtail (*P. palamedes*) are among the few insects that can detoxify or sequester the poisons, and they specialize on *Persea* (cf. Lederhouse et al. 1992, Carter and Feeny 1999).

There are perhaps 200 tropical Asian and American species in *Persea* (Mabberley 1997). Many of them are part of local pharmacopoeias, but none is as famous as the avocado. Although most people know that species as the primary ingredient passed down from the Aztecs almost without change in the recipe for *guacamole* (Coe 1994), few realize that it is also medicinal. The leaves and other parts contain a variety of toxic compounds that are dangerous to vertebrates if consumed in quantity (Hargis et al. 1989, Grant et al. 1991, McKenzie and Brown 1991, Stadler et al. 1991, Burger et al. 1994, Oelrichs et al. 1995). In spite of the toxic chemicals in the leaves, Latin Americans regularly use them in small quantities as a spice. They give foods an anise flavor (Hearon 1993). Those same compounds show potential as insecticides (Oberlies et al. 1998) and give some protection against *Giardia* (Ponce-Macotela et al. 1994).

Avocado and other species in the genus show considerable dietary and medicinal potential (Zanobi et al. 1974, Meade et al. 1980, Mohan and Kekwick 1980, De-Oliveira et al. 1985, Ballot et al. 1987, Ma et al. 1989, Sheldon et al. 1990, Guevara et al. 1994, Eccleston and Harwood 1995, Kimura et al. 1995, Koua et al. 1998, Castro et al. 1999, Chiapella et al. 2000, Domergue et al. 2000, Kim et al. 2000, Kruthiventi and Krishnaswamy 2000, Caballero-George et al. 2001, Hashimura et al. 2001, Kawagishi et al. 2001, Kut-Lasserre et al. 2001, Schlemper et al. 2001, Stucker et al. 2001, Lequesne et

al. 2002). Therefore, their congener *P. borbonia* is showing the same patterns as its relatives. In spite of its extreme importance among indigenous people in the south-eastern United States, red bay has never appeared in the journal *Economic Botany* (Kaplan 2001).

Although modern southern culture owes as much to the Creeks as any group of people, their botanical heritage has been slighted (Hudson 1976). The Creeks and their relatives the Seminoles were aware of all the bays. Bartram ([1791] 1958) told us Creeks called *P. borbonia* the *eto miko*, and *Magnolia grandiflora* was *tolochlucco* (big bay). By the 1950s, the Seminoles had shortened those names to *to:li* and *to:lhátki* (white bay, *M. virginica*). What will be remembered in the next 200 years?

### *Phalaris*

(Greek *phalaris*, *phaleris*, used by Dioscorides, fl. A.D. 40–80, for some kind of grass; presumably from *phalaros*, having a patch of white or crest, alluding to the inflorescence)

*alpiste* (French)

*canaria* (Italian); canary-grass (“canary,” referring to the Canary Islands or *Canariae Insula* [Isles of Dogs], a name used by Pliny, A.D. 23–79); *kanarigras* (*kanari*, canary, *gras*, grass, Norwegian)

*Glanzgras* (*glanz*, shiny, *gras*, grass, German)

*phalaride* (French)

reed-grass (a name most often used for *Phragmites*)

*ror-flen* (*ror*, reed, *flen*=?, Swedish)

*scagliola* (Italian)

*strandror* (*strand*, seashore, *ror*, reed, Norwegian)

***Phalaris caroliniana*** (of Carolina)

*baabkam* [*papkam*] (pi., *baahpakam*) (“it has a grandfather,” Akimel O’odham [Pima]; **Rea’s** informants could not give him a reason for the name; he speculated it must be an ancient poetic allusion)

Carolina canary-grass [canarygrass]

may-grass [maygrass] (“May-grass” was in use by 1830, but applied to *Panicum latifolium*; apparently applied to *Phalaris* ca. 1974, originally by archaeologists)

Europeans knew at least three species of *Phalaris* when they arrived in the New World. Reed canarygrass (*P. arundinacea*) and Harding grass (*P. aquatica* L.) were grown for hay, while seeds of canary grass (*P. canariensis*) were eaten by people. There are about 20 species in *Phalaris*, with 7 native to Europe (Mabberley 1997). *Phalaris caroliniana* was named by Walter in 1788, and now grows from Florida to California and Mexico, north to Maryland, Tennessee, Missouri, Kansas, Colorado, and Oregon.

May-grass is a starchy-seeded annual grass whose grains (caryopses) are dominant in Middle and Late Woodland archaeological sites (Crites and Terry 1984, Asch and Asch 1985). The grains have been associated with people in Illinois, dating 1700+70 B.P. in one site and 1400+70 B.P. at another site. It was already an important cultivated food in

Kentucky in 1000 B.C. Fritz (2000b) concluded that it was a domesticated crop by 3000 B.P.

Moerman (1998) found the species being used only by the Gila River Pima, based on a report by Amadeo Rea. Subsequently, Rea (1997) provided more information on may-grass use. While reading through a 1908 report by Frank Russell, Rea noticed an unidentified grass the O’odham had called *papkam*. He realized that it was what modern people call *baabkam*. Russell wrote, “The heads are tied in bunches and dried in the sun. They are then shelled, screened, the seeds parched, ground on the metate, and eaten in pinole. They are ‘not sweet.’” One of Rea’s O’odham friends had told him the seeds were once eaten but did not taste good. These grasses are another member of the Eastern Agricultural Complex that was abandoned when maize agriculture became widespread.

### *Phaseolus*

(From Greek *phaseolos*, a little boat, light vessel, referring to the similarity between the pod and the craft; used by Dioscorides, fl. A.D. 40–80, for what Agnes Arber identified as *Vigna unguiculata*, cf. Meyer et al. 1999; known as *faseolus* or *phaseolus* to Romans)

***Phaseolus polystachios*.** From Britton and Brown 1897.

***Phaseolus polystachios*** (many-spiked)  
[thicket, wild] bean [vine]  
*sacsac* (Delaware)

***Phaseolus vulgaris*** (common)  
*acayotle* (maybe from *acatl*, cane, *etl*, bean, Náhuatl, recorded by Humboldt fide Hedrick 1919)  
*aift* (Garifuna)  
*añkonaki* (Ofo)  
*assentemmens* (Strachey [1612] 1953 compared these beans with Italian *fagioli*, Powhatan, Virginia)  
*a'teba'kwe* (Abenaki, Maine)

*bala* (Choctaw); *bala* (Chicksaw); *palaná* (Koasati), *salá:li* (Mikasuki); *tlako* [*ta:ko*] (Creek, Muskogee); *tobi* (Choctaw)

[common] bean (“bean” from Old English *béan*, perhaps cognate to Latin *faba*, but some think that doubtful); *Bohne* (German)

*bisoloma* (Arawak, Suriname)

*cannellini* (Italian name for a large white kidney bean)

*chin* (Jicaque, Honduras)

*etl* (bean, Nahuatl); *exotl* (green bean still in the pod, Náhuatl)

*fagiolo* [*fagiuolo*] (from Latin *faseolus*, Italian); *feijão* (from Latin *faseolus*, with a change in the suffix, Portuguese); *frijol* (Spanish); *phaséole* (French)

French-bean (called French or Roman beans in 1632, probably because they were imported from the Mediterranean area into northern Europe)

haricot (etymology uncertain, from French *haricot*, shortened in the 1600s from *hericoq de mouton*, of the 1300s, a stew usually of mutton, reapplied to the beans about 1653; in 1693, Joannes de la Quintyne used both *aricos* and *haricauts* in his book *The Compleat Gard’ner*)

*hon-bthin-ge* (Osage)

*húce* [*nuntce’*, *yúce*] (Catawba)

*hyni*<sup>3</sup> (Chinantec, Oaxaca)

kidney-bean (a reference to the similarity of shape between the beans and human organ; used by Turner in [1548] 1965 as “kydney beane”)

*kima’t ta’l* (*kima’ti*, middle, *ta’l*, inside, Atakapa)

*koje’s* (Potawatomi)

*malachxil* [*malachxitall*] (Delaware, New Jersey)

*miskodissimi* (Potawatomi); *mushaquissedes* (Pequod, Rhode Island, Connecticut)

navy bean (specifically meaning the dried, white haricot, in English by 1856)

*ogaressa* (Huron, Ontario)

*okindgier* (beans in pods, Carolina Algonquians); *okinsher* (Powhatan, Virginia)

*ossahèta* (Onondaga)

*peccataas* [*peketawes*] (recorded by Strachey in [1612] 1953, Powhatan, Virginia); *peswe’min* (Plains Cree)

pinto bean (apparently first applied in English to the spotted beans of the southwestern United States in 1916)

*pònair Fhrangach* (French beans, Gaelic)

*purutu* (Quechua, Peru)

*sahe* [*sahu*] (Micmac?, St. Laurence)

*si’hpari* (Tunica)

snap bean (in use since 1770 for the green pods that are broken into pieces and cooked as a vegetable while still young)

*tsodi* (Yuchi)

*tantka* (Biloxi)

*teppuhguam-ash* (twiners, Algonquian)

*tuya* (Cherokee)

*wickonzówer* (pleasant when cooked, Carolina Algonquians)

When I was growing up, beans were a part of each noon and evening meal. My mother varied the dishes; sometimes they were white beans, and sometimes brown or pintos. Seasonally, we had green beans. I always liked the beans the second time a dish was served because they were then cooked to mush. Little did I know that Algonquian people of coastal Virginia preferred them that way too in the 1580s when Thomas Harriot was there.

Classical mention of “beans” and the early introduction of American plants into Europe caused confusion about their nativity for hundreds of years. Indeed, Columbus saw beans on his first voyage in 1492, and brought them back to Spain in 1493. Of the plants he saw in Cuba, Columbus wrote of “fields planted with *faxones* and *habas* very different from those of Spain” (Hedrick 1919). Jane and Skelton (1960) corrected the name *faxones* to “beans,” and *habas* as “kidney beans” although Columbus thought the former was *Vigna unguiculata* and the latter *Vicia faba*. Their translation is what he saw, not what he thought he saw.

*Phaseolus vulgaris* reached England in 1594 (Hawkes 1998). Leonard Fuchs in 1542 thought what we now call *P. vulgaris* was the bean of classical Rome and Greece and called them *Faselen*. Similarly, Hieronymus Tragus in 1552 and Davidus Kyber in 1553 thought the same as Fuchs. That view held until the late 1800s, but it has subsequently been confirmed that *Phaseolus* is a New World crop (Smartt and Simmonds 1995). Archaeological studies indicate beans in Mexico by 6000–7000 B.R., and in Peru 7000–8000 B.P. (Smartt and Simmonds 1995, Kaplan and Lynch 1999, Lentz 2000). They reached eastern North America some time after those dates (Fritz 2000b), apparently between 700 and 1000 B.R.

Beans were widely cultivated among the northern Florida tribes before Europeans arrived (Hedrick 1919). Pánfilo de Narvaez found beans in western Florida in 1528, as did Hernando de Soto in 1539 (Swanton 1936, 1946). Similarly, Jean Ribaut found beans cultivated by the Timucua in northeastern Florida in 1562.

Earlier explorers also found beans farther north (Hedrick 1919). Florentine navigator Giovanni da Verrazzano (alias John Verazanno) (1485–1528) found them among the indigenous people of Norumbega, Maine, in 1524. As the first European visitor to the New England coast, he had never before seen kidney beans. He wrote of the people, presumably the Pequot, “Their ordinarie food is of pulse, whereof they have great store, differing in colour and taste from ours, of good and pleasant taste.” Later, Jacques Cartier found beans “of every color” among the Hurons at the mouth of the St. Lawrence River of Quebec in 1535.

In the same region, Samuel de Champlain (1567–1635) found the Abenaki of the Kennebec River on southern Maine eating multicolored beans in 1605, and Capt. John Smith (1580–1631) knew them among the New England tribes in 1614 when the Pilgrims first landed. Before 1670, John Josselyn wrote of “French beans: or rather, American beans. The herbalists call them kidney-beans from their shape and effects: for they strengthen the kidneys. They are variegated much, some being bigger, a great deal, than others; some white, black, red, yellow, blue, spotted” (Hedrick 1919).

Harriot ([1590] 1972) wrote of North Carolina that the *okindgier* was “called by vs beanes, because of in greatnesse and partly shape they are like to the Beanes in England, sauing that they are flatter, of more diuers colours, and some pide. The leafe also of the stemme is much different. In taste they are altogether as good as our English peaze.”

Beans are documented as grown for food among the Abenaki, Algonquin, Apache, Aztecs, Cherokee, Choctaw, Creek, Delaware, Havasupai, Huron, Iroquois, Menomin, Navajo, Ojibwa, Onondaga, Papago, Pequod, Potawatomi, Santee, Seminoles, Sia, Tewa, Tuscarora, and Zuni (Romans [1775] 1961, Bartram 1719, Hedrick 1919, Smith 1933, Swanton 1946, Berkeley and Berkeley 1982, Moerman 1998). All the agricultural tribes in the eastern United States surely made use of them.

Harriot ([1590] 1972) wrote that the people of Virginia cooked corn and beans together to “make them victuall either by boyling them all to pieces into a broth; or boiling them whole vntill they bee soft and beginne to breake as is vsed in England, eyther by themselues or mixtly together: Sometime they mingle of the wheate with them. Sometime also beeing whole sodden, they bruse or pound them in a mortar, & therof make loaues of lumps of dowshe bread, which they vse to eat for varietie.” Romans ([1775] 1961) found the Choctaw doing much the same by boiling corn and beans together, and calling it *holhponi*. We now call this mixture “succotash” (an Algonquian word akin to Narraganset *msekwtas*; in use by 1751). Capt. John Smith recorded for Virginia a dish of unripened corn, roasted in hot ashes, and eaten boiled with beans during the winter. He called it *pausarowmena* or *pausarawmena*. Le Page Du Pratz found the Natchez in 1758 cooking corn bread with beans, a dish they called *co oëdlou* (Swanton 1946).

The Caddo of southwestern Arkansas, northwestern Louisiana, and adjacent Texas had a unique bean dish. Henri de Joutel wrote about 1615 that they “do not make much mystery in preparation of them.” These people cooked them in a big pot without any preparation and kept them covered with leaves until they were almost done. Then, they poured warm, salted water over them before serving. Those eating the pods were expected to eat strings, stems, and other parts or remove the pieces they did not want (Swanton 1946). This tribe was also unusual in salting their food.

By the time Bartram ([1791] 1958) was among the Seminoles of northern Florida in the 1770s, he found them growing “beans” (*Phaseolus*). They were also growing what he called “pease,” the introduced cowpea, *Vigna unguiculata*. Indeed, along with native produce, Bartram recorded a number of other introduced plants among these villagers.

At Palatka (from Creek *pilotaikita*, crossing), in what is now Putnam County, Florida, Bartram visited a Seminole garden. The field was planted “chiefly with corn (*Zea*), Batatas [*Ipomoea batatas*], Beans [*Phaseolus vulgaris*], Pompions [*Cucurbita pepo*], Squashes (*Cucurbita verrucosa*) [*C. pepo*], Melons (*Cucurbita citrullus*) [*Citrullus lanatus*], Tobacco (*Nicotiana*) &c. are abundantly sufficient for the inhabitants of the village.” At the same village he later wrote, “The fields surrounding the town and groves were plentifully stored with” exotic crops including peas (*Vigna unguiculata*), potatoes (*Solanum tuberosum*), peaches (*Prunus persica*), figs (*Ficus cairica*), and oranges (*Citrus sinensis*).

Later Bartram visited Cuscowilla (*taska*, warrior, *weli*, plunderer, Choctaw), near the northwestern corner of Tusawilla Lake, and east of the present Micanopy, Alachua County, close to the Alachua savanna. There the Seminoles planted, “but little here about

the town, only a small garden spot at each habitation, consisting of a little Corn, Beans, Tobacco, Citruls [*Citrullus lanatus*], &c.” Instead, they had their major crops elsewhere.

Bartram also described an extensive maize field near Cowee (a Cherokee town formerly on the Little Tennessee River, Macon County, NC). He rode “near two miles through Indian plantations of Corn, which was well cultivated, kept clean of weeds and was well advanced, being near eighteen inches in height, and the Beans planted at the Corn-hills were above ground.”

Sturtevant (1955) found the southern Florida Seminoles growing what the Miccosukee called *sala*: *Ikitiscî* (red bean), *sala:lláknî* (yellow bean), and *sala: llákno:cî* (small yellow bean). The beans were *Phaseolus vulgaris*.

Fernald et al. (1958) indicate that *P. polystachios* is edible, and Freytag and Debouck (2002) concur. Both books, however, point out that there are few seeds borne on the plants and that they are small. Both Uphof (1968) and Hocking (1997), on the other hand, write that the seeds are a popular food, being dried and cooked. Uphof (1968) wrote they were “highly prized by North American Indians.” Since Moerman (1998) did not list the species I wonder where Uphof got his information. However, our expert on *Phaseolus*, Lawrence Kaplan, wrote me (Apr. 2003), “When I was trying crosses...[i]t produced well in the greenhouse, certainly enough to warrant gathering.”

Beans have been so important to Europeans and other settlers in the New World that expressions have grown up around them. Generally they have a good reputation, and that led to the saying that someone is “full of beans.” That phrase means that the person is in an energetic, cheerful mood (Davidson 1999). The expression in Portuguese is *cheio de feijão*.

There is an impolite rhyme dealing with the difficulties humans have digesting the proteins in *Phaseolus*. This incomplete digestion results in an unusually large amount of methane, and subsequently flatulence. As an ancient saying goes:

Beans, beans, the wonderful fruit.  
The more you eat, the more you toot.  
The more you toot, the better you feel.  
That’s why I eat beans at every meal!

### *Phlebodium*

(Greek *phlebodes*, full of veins; John Smith moved Robert Brown’s section *Phlebodium* to generic level)

***Phlebodium aureum*** (golden, in reference to the rhizome scales)

(=*Polypodium aureum*)

*avenca dourada* (golden fern, Brazil)

cabbage palm fern (Florida)

*calaguala* [*calahuala*] (Cuba, Veracruz, Honduras, Panama)

*istimá:ha imaná* (*este*, person, *im*, his, *aha*, tuber, *em*, its, *mahe*, height, Creek); *yá:tcáyhimá:hî* (*yá:tcáyh*, tall person, *im*, his, *á:hî*, tuber,

***Phlebodium aureum*.** Drawn by  
P.N.Honychurch.

Mikasuki); *yaatchayhen taapente* (tall person's fern, Mikasuki)  
*mono de león* (lion's paw, Totonac, Veracruz)  
*ni<sup>23</sup> za<sup>3</sup>* (Chinantec, Oaxaca)  
 [golden] serpent fern (Florida, Bahamas)

Linnaeus ([1753] 1957) called this fern *Polypodium aureum*, following Charles Plumier's *Polypodium majus aureum* (big red fern) of 1693. Many people still agree with him, but others segregate this and two to four other species into *Phlebodium* following John Smith (1798–1888) and Nauman (1993).

The name *calaguala* is widespread in Latin America for ferns famous as medicines (Duke and Vasquez 1994, Gupta 1995a). While that name subsumes several species, the most famous has been *Polypodium calaguala*, a South American species. However, people from Cuba through Veracruz, Mexico, and south through Guatemala, Honduras, and Panama mostly use *P. aureum* (Gupta 1995a). Cubans consider the rhizome of *P. aureum* good to treat wounds, falls, and external sores (Roig 1945). They also consider *P. aureum* anthelmintic and sudorific, and use it to treat rheumatism, heart disease, high blood pressure, asthma, and colic. Totonacs in Veracruz use *P. aureum* to treat coughs, internal bruises, and the kidneys, and in medicinal baths (Vásquez and Jácome 1997). In northern South America, Duke and Vásquez (1994) comment that *calaguala* is the first plant mentioned when medicinal plants, particularly treatments for cancer, are discussed. Florida is the northern limit of this fern.

A primary use of the fern among the Seminoles is for chronic sickness that had not responded to other treatments (Sturtevant 1955). Typically, the mixture for chronic sickness is a combination of many plants called *ayikctanahkó:cí* (small gathered medicine, Mikasuki) or *atilo:kocí* (*vetelokv*, gathered, *oce*, small, Creek). *Phlebodium aureum* is one of four ferns that might be included. Another mixture is given for “insanity,” any kind of confusion or odd behavior (Sturtevant 1955). Still another use is during childbirth.

Gupta (1995a) reported that an ethanolic extract of cabbage palm fern showed activity against certain viruses. It has not been confirmed that the species has the same activity as others called *calaguala*.

***Phoradendron***

(Thomas Nuttall named this with Greek *phoros*, bearing, *dendron*, tree)

***Phoradendron leucosperma*.** From Britton and Brown 1896.

***Viscum album*** (although European mistletoe is placed in a genus distinct from the American plants, they differ in technical details; people familiar with the plants in Europe would have had no trouble recognizing the eastern North American species)

*druiddh lus* (*druiddh*, Druid, *lus*, herb, Gaelic); *gui* (French); *guis* (sticky, Irish)

mistletoe (a word from Old English in use by A.D. 1100; from *mistle*, dung, and *tan*, twig; akin to Old High German *mistil*, mistletoe, and *zein*, twig; the name came into existence because people believed that the mistle thrush, *Turdus viscivorous*, excreted the seeds on limbs; it actually scrapes them off its bill; see Austin 1998a); *Mistel* (German); *misteltein* (Norwegian); oak mistletoe (USA)

*muérdango* (Spanish)

*uil'-ioc* (all-heal, Gaelic)

*vischio* (from Latin *viscos*, sticky, Italian); *visco* (Portuguese)

*Vogel-liem* [*Vogellym*] (birdlime; cf. Turner [1548] 1965)

***Phoradendron leucocarpum*** (white-fruited) (= *P. flavescens*, misapplied)

*a:tilhiciksó imitto* (*a: tilhiciksó*, elf, *im*, his, *ittó*, tree, Koasati)

*anteka' nûta'wayi'* (Biloxi)

*fani shapha* (*fani*, squirrel, *shapha*, flag, Choctaw); *fanishapha'* (*fani'*, squirrel, *im*, its, *shapha'*, flag, Chickasaw); *ipfiäsapha* (squirrel's flag, from *ipfo*, squirrel, *im+sapha*, its flag, Alabama)

*fani' hasimbish* (*fani*, squirrel, *hasimbish*, tail, probably is this plant, Chickasaw)

*gui* (mistletoe in French, Houma, Louisiana)

*hin'fimasókci* [*hinrimdsokci*, *henle* 'mashokche] (squirrel tea, Mikasuki)

*'to eleko [ito-iliko, toiliko, tuhiligu, eto-eleko, tóhelleko, tohiríkko, tohifíkko, toheleko] (eto, tree, eleko, feet, Creek, Muskogee)*  
*uda'li* (it is married, Cherokee)

Mistletoe has a long association with native people throughout the eastern United States, much as it has among the Europeans. The Cherokee, for example, used it to treat headache, epilepsy, in “medicine for pregnant women,” to lower high blood pressure, and to cure vomiting (Hamel and Chiltoskey 1975). Among the Muskogean people, the Chickasaw made a remedy from it to treat “Red Squirrel Sickness” (toothache, swollen jaw, and sometimes nosebleed) (Swanton 1928a,b). The Houma made a decoction of the plant to aid debility and paralytic weakness, considering it something of a panacea (Speck 1941). The Yuchi use it to treat “Raccoon Sickness” (diarrhea, usually in babies) (Howard 1984). The Creeks made medicine from leaves and branches for lung troubles, including consumption (Swanton 1928a). The Florida Seminoles use it to treat “Deer Sickness” (numbness, painful limbs and joints), as an emetic during ceremonies, and as a medicine for chronically ill babies (Sturtevant 1955). The Oklahoma Seminoles make an infusion of leaves and berries for ringworm sores and to treat hemorrhoids, and give it to children for whooping cough (Howard 1984). Modern Florida Seminoles include it as part of the “Death Medicine” (Snow and Stans 2001).

### *Phragmites*

(From Greek *phragma*, hedge, fence, or screen, plus *-ites*, resembling; the word was used by Pliny, A.D. 23–79, for a reed)

*Phragmites australis* (southern)  
*abo'djigun* (something turned out or over, Ojibwa)  
*act* (Atakapa)

***Phragmites australis*.** Drawn by Mary Wright Gill and Agnes Chase. From Hitchcock and Chase 1950.

*aqraban* (Bahrain)

arrow [bamboo] grass

*atask* (Strachey wrote *attasqwas* in [1612] 1953, and Capt. John Smith penned *attaskuss* for the Powhatan word; both called them “weeds” but Smith added “grasses”; the root /\*aTw-/ occurs in their word *atoms*, for “arrow”); cognates include *assa-kanask* (Ojibwa); *asta-kanask* (Cree)

*bennels* (from Hedrick 1919, source not traced)

*caña de Indio* (Indian cane, Panama, Puerto Rico); *caña de pantano* (marsh cane, Puerto Rico); cane grass [wild cane] (New Mexico); *cañoto* (wild cane)

*carrizo* (Arizona, New Mexico, Sonora to Honduras, Hispaniola)

*chaume* (more often applied to straw as for a thatch roof, from Latin *calamus*, French)

*hajna* (Saudi Arabia)

*halal* (cane like corn stalks, Maya, Yucatan)

*ihya* (Cherokee)

*kaneh* [*qáneḥ*] (Hebrew)

*koha:ha:kâ* (*kohv*, cane, *vhake*, replica, Creek); *olâ:nâ:bî* [*orâ:nâ:bî*] (cane replica, referring to *Arundinaria*, Mikasuki); *kunshak* (Choctaw); *oskoba* (from *oski holba*, resembling cane, Choctaw; a local synonym for *kunshak*)

*lók'aa'* (Navajo)

pull reed ("A long reed used for ceilings instead of laths"; cf. Britten and Holland [1886] 1965); [common] reed [grass] (Florida to New Mexico, Bahamas, Puerto Rico Panama); *riet* [*rietje*, *rif*] (reed, Dutch)

*Rohr* (from Gothic *Raws*, German); *takrør* (roof reed, Norwegian)

*roseau* (from Old French *ros*, related to German *Raus*, French); *roseau commun* (Quebec); *petit roseau* (little reed, Guadeloupe, Martinique)

*saesgean* (also an area dominated by moors or fens, Gaelic)

*sak-halal* [*zak-halal*, *zachalal*] (*sak*, white, *halal*, cane-like corn stalks, Maya, Yucatán)

*soccos* ("seed" cane, for planting, Spanish)

*taa gui* (*taa*, mat, matting, *gui*, cane, Zapotec)

*tibisi* (reed, Taino, Cuba, Hispaniola)

*tlh'ogh elgha" nachel ghi"la* (grass which is connected together, i.e., large nodes, Chipewyan, Canada)

*wa:pk* [*vaapk*] (O'odham, Arizona, Sonora)

*xapij* (Seri, Sonora)

The next time you listen to orchestra music, remember that you owe many of the sounds to plants. Stringed instruments and woodwinds (oboes, clarinets, bassoons, etc.) are made partly or completely of wood. However, the topic here is the music coming from the woodwinds, due to plant parts called reeds.

The word "reed" applies to several different plants, but three species are native to Florida. One is the musical reed source (*Phragmites*), one for fishing poles (wild cane; see *Arundinaria gigantea*), and the other is wild bamboo (see *Lasiacis divaricatd*), which currently is not used by people in Florida. People elsewhere in the Americas use all three and distinguish between them with common names, while at the same time noting their similarities.

Moreover, the words "reed," "cane," and "bamboo" are intermixed in current and historic usage. All originally had somewhat different meanings and origins, yet those words and "calumet" all came into English because of plants (see also *Arundinaria*; *Lasiacis*).

The oldest of these terms is "reed." That word is related to Old English *hréod*, Old Frisian (*h*)*reid*, Old Saxon *hriad*, and Old Teutonic *hreundo*, all meaning tall straight stems of grasses. Originally, reed applied to either *Phragmites* or *Arundo*. "Reed" dates from ca. A.D. 725, being equated in a publication that year to *harundo* and *canna*. Although similar, *harundo* is not related to Latin *hirundo*, the swallow.

Obviously, the concepts of reed, cane, bamboo, and pipe are all interrelated and applied to numerous plants. The first requirement is that the grasses are comparatively large and have either a woody stem or one that is somewhat lignified. The most useful part of the grasses is the stem, and that has served people throughout the world in many ways.

Perhaps at least partly because *Phragmites* is most widely distributed, it is a well-known plant (e.g., Howard and Powell 1963, Kenk 1963, Baranov 1967, Core 1967, Johnston 1970, Morton 1970, Turner and Bell 1971, de la Cruz 1978, Heiser 1978, Bailey and Danin 1981, Wolverton 1982, Cunningham and Milton 1987, Timbrook 1990). The species grows from southern Canada to the central United States, to California, Louisiana, Florida, the West Indies, and from Mexico to Chile and Argentina. *Phragmites* also grows widely in Europe, Asia, Africa, and Australia. The genus *Phragmites* was created by French botanist Michel Adanson who called it that because the grass grows along streams and “fences” them from nearby areas. These are the plants called *kaneh* or *qáneh* in Hebrew versions of the Bible (Zohary 1982), and ancient Egyptians used the culms as “quill” pens. *Phragmites* was well known to the Europeans when they first arrived in the Americas.

In the New World, Europeans continued their old names for the plants. Dutch speakers use a word closest to English, when they say *riet* [*rietje*, *rif*]. The Germans call the reed *Rohr*. The French borrowed that term and say *roseau* (from Old French *ros*). Speakers of French also have a Latin derivative, *chaume* (from Latin *calamus*), but this is more often applied to straw as for a thatch roof. Romance languages continued using their Latin-based words, in Portuguese *cana*, Spanish *caña*, and Italian *canna*. Gaelic speakers called it *saesgean*, which also means an area dominated by moors or fens.

Europeans in the Americas also compared *Phragmites* with the Old World sugarcane (*Saccharum officinarum*), saying *caña de Indio* (Panama, Puerto Rico) and *soccos*. They use that comparison because both plants provide sweets. Fernald et al. (1958) described the process of *Phragmites* extraction. Stems are gathered before flowering, dried in the sun, and ground or beaten into flour. The finer parts are sifted out and moistened to make a gummy mass that is roasted by a fire until it swells and browns slightly. The material is eaten like taffy or marshmallows.

There is also a sweet edible gum exuded from damage caused by insects (the mealy plum aphid, *Hyalopterus arundinis*). Although Hodgson (2001) suggested that the use of the sweet extract from *Phragmites* called *manna* by the Europeans and *cadece* (juice of the reed) by the Cochimis was originally restricted to the California area, its use seems to have been more widespread. It may be the abundance of historical documents from the California region that gives the impression of a focus there. Many people, including Akimel and Tohono O’odham (Pima and Papago), Paiutes, Panamints, Yavapais, Cocopas, and others certainly showed the Europeans the sweet material. Europeans then left behind written accounts.

Other native American names compare *Phragmites* with cane (*Arundinaria gigantea*) or maize (*Zea mays*). The Seminoles say *koha:ha:ká* (Creek) and *otá:ná:bi* (Mikasuki), referring to *Arundinaria*, which they call by the simple terms *kohá* (Creek), *kóha* (Muskogee), or *otá:ni* (Mikasuki). In Yucatán, the Maya say it is *halal* (cane-like corn stalks), or *sakhalal* [*zak-halal*, *zachalal*] (*sak*, white, *halal*).

From British Columbia through the western United States to Panama, the young shoots are served as a potherb (Fernald et al. 1958, Duke 1968, 1972, Moser and Felger 1985, Hodgson 2001). In the 1870s the English botanist Mrs. Phoebe Lankester noted that the young shoots, especially where protected from light, “made an excellent pickle” (Fernald et al. 1958). As late as 1942, Mr. and Mrs. Whittrock commented that indigenous people in New Jersey boiled the rhizomes like potatoes, and in the early

spring they cooked the young shoots like asparagus (Fernald et al. 1958). The rhizomes may be harvested during any season and eaten raw or ground into flour.

The seeds are hard to extract from the chaff, but they were cooked and eaten by people from New England to Oregon and south to the Sonoran Desert and probably elsewhere (Fernald et al. 1958, Mabberley 1997, Hodgson 2001). Sometimes the chaff was allowed to remain on the seeds. Again in New Jersey, the Whittocks recorded that local indigenous people did not remove the hull, but cooked the whole grain into a reddish gruel, colored by the hull. They added that it was “wholesome as a food, though not too appetizing in appearance” (Fernald et al. 1958).

People from the Thompson of British Columbia and the Okanagon of the Washington and Canada border to the Zapotecs of Oaxaca use *Phragmites* to prepare mats (Reko 1945, Mabberley 1997). Surely, people in the eastern parts of North America did the same although they made more use of cane (see *Arundinaria*). Some of the mats were used to dry food, while others were for sleeping and other purposes (Rea 1997, Moerman 1998).

In the southwestern United States and probably elsewhere in its range, *Phragmites* stems have been used to make many items. One of the most frequent applications before indigenous people obtained guns was as shafts of arrows and atlatl darts. There are records of at least the Apache, Aztecs, Havasupai, Hopi, Hualapai, Kawaiisu, Klamath, Navajo, Paiute, and Tewa making arrows from them (Elmore 1944, Ebeling 1986, Mabberley 1997). Some other uses include making baskets, boats, containers, flutes, nets, pipes (or “cigarettes”), pipe stems, prayer sticks, roofing, screens, thatching, and weaving rods (Kearney and Peebles 1951, Felger and Moser 1985, Ebeling 1986, Mabberley 1997, Hodgson 2001). Both stems and leaves were used to make cordage for nets and snares (Ebeling 1986).

We can still purchase *Phragmites* reed “screens” to use as visual barriers along fences and other areas. In addition, the species is used commercially to make paper, cellophane, cardboard, synthetic textiles, fiberboard, fuel, alcohol, insulation, and fertilizer (Hocking 1997). The Seminoles probably also used reed much as they did cane (see *Arundinaria*).

In the southeast, only the Seminoles are recorded as using *Phragmites* as medicine. These people used the hollow stems as a tube to blow medicine into wounds or onto skin problems, and even as a medication for boils and carbuncles (Sturtevant 1955). Similarly, the Navajo use *lók’aa* for stomach and skin problems (Mayes and Lacy 1989). The Apache made a medicine to treat diarrhea and other digestive problems (Moerman 1998). The Blackfoot made a decoction of the whole plant as an emetic. The Iroquois mixed *Phragmites* with bottle-brush grass (*Elymus hystrix*) to make “corn medicine,” a mixture in which they soaked corn kernels before planting them. In the Bahamas and Cuba, a root decoction of *Phragmites* is taken as a diuretic and antiseptic. On North Caicos the root is boiled with *Chiococca alba* to relieve “pain in the back” (kidneys) (Roig 1945, Morton 1981).

Human alterations of landscapes have resulted in major changes in reed abundance. Formerly, when the land was wetter, people in the southwestern part of the United States and nearby Mexico named places because of the stands of *Phragmites*. Some examples include Carrizo, Carrizo Butte, Carrizo Mountains, Carrizo Ridge, and Carrizo Wash (Apache County, Arizona), Carrizo Creek (Catron County, New Mexico), Carrizozo (Lincoln County, New Mexico), *Xapij an Hax* (reedgrass inside water), and *Hax Cdail* or

*Pozo Carrizo* (Kino Bay, Sonora). Now, drainage has resulted in near disappearance of the species. The alternate situation applies in the eastern states where the apomictic form has become a weed covering vast areas in monocultures.

“Reed” in woodwinds is a slightly different meaning from all the others. There, a segment of the stem is removed and thinned so that air moving over it in the confined space of the instrument will cause it to vibrate. Sounds from that vibration are amplified by the remainder of the instrument to produce the music. Occasionally, the reeds are made of *Arundo donax*, another reed; however, the preferred “reed” is from *Phragmites*. No other plant produces sounds as pleasing as it, and synthetic products are usually not acceptable to the musicians who demand excellence in sounds. An ancient grass used to make Greek panpipes is still the best.

### *Phryma*

(Derivation unknown; possibly from Greek *phryna*, a toad)

***Phryma leptostachya*.** From Britton and Brown 1898.

***Phryma leptostachya*** (slender-spiked; an old generic name)

[American] lopseed (“lop,” to hang loosely, was in English by 1578; “lopseed” was recorded in a common name by 1850)

Apparently, the first that Europeans learned of these herbs was from Jan Gronovius’s *Flora Virginica*. In 1739, he called the plants *Verbena racemosa simplicissimo, flores sessilibus, calycibus fructus reflexis racemoque appressis* (A verbena with a simple raceme, flowers sessile, the fruiting calyx reflexed and appressed to the raceme). In 1740, Adrian van Royen used the same phrase to describe plants growing in the Netherlands. Not long afterward, in 1751, Linnaeus coined the generic name *Phryma* and left everyone wondering on what he based the name. *Species Plantarum* (Linnaeus [1753] 1957) states simply, “*Habitat in America septentrionalis*” (Grows in North America).

That problematic etymology of the generic name set the stage for trying to understand the relationships of these plants. They have been put in their own family, the Phrymaceae, or the Verbenaceae. The most recent molecular genetic studies support *Phryma* being removed from the other families and recognized as a distinct lineage (Wagstaff and Olmstead 1997).

Although Linnaeus did not know it when he named the herbs, the genus is disjunct between Asia and North America. There has been a tendency to call the Old World plants a different species from the American, but the differences are minor (Kara 1969). Since the late 1960s, most have considered them a single, bicentric species in the monotypic *Phryma*.

In North America, the plants are considered native from New Brunswick to Manitoba, south to Florida, Alabama, Louisiana, and eastern Texas (Fernald 1950, Steyermark 1963, Barkley 1986, Jones and Coile 1988, Diggs et al. 1999). These plants are widespread and important medicines in Asia, but few records exist of their application in the Americas. The Ojibwa chewed roots or gargled a root decoction to relieve sore throat, and drank the decoction when they had rheumatism (Densmore 1928, Moerman 1998).

Hocking (1997) noted that the leaves and roots are insecticidal and have been used to kill houseflies in Japan and China. Elsewhere in Asia, the plants are used to treat fevers, ulcers, ringworms, scabies, boils, carbuncles, and cancers (Hsu 1986, Foster and Duke 1990). The herbs contain phryumarol, a sterol (Hocking 1997).

### *Phyla*

(João de Louriero, 1717–1791, used Greek *phyle*, a tribe or clan, an allusion to the many flowers in tight heads)

fog fruit (in use for *P. nodiflora* in the Americas by 1886; the old meaning of “fog” was for “grasses” that sprang up in fields immediately after the hay was harvested; that sense dates from the 14th century A.D.; the concept of moisture in the air did not appear until the 1500s, although it now precludes the older use); frog fruit (corruption of “fog fruit”)

***Phyla lanceolata*.** Drawn by Vivian Frazier. From Correll and Correll 1972.

***Phyla lanceolata***  
lance-leaf fog-fruit

***Phyla stoechadifolia*** (leaves resembling those of the mint *Lavandula stoechas*) (= *Lippia stoechadifolia*)  
azulejo (little blue one)

epazotillo (little epazote, *Chenopodium ambrosioides*, Totonac, Veracruz)

guia huace [*quie huace*] (guia, flower, huace, smell of roses or sweet fruit, Zapotec, Oaxaca) kabalyaxmik [*cabalyaxnic*] (kabal, small plant, ya 'ax, green, nik, joined to, in other words, small plant that grows with the ya 'ax che', *Ceiba pentandra*, the green tree that supports the world; Maya, Yucatan)

marsh phyla (a book name)

orozús (literally, "juicy-root," a name usually given to a legume, Belize)

poleo [*poley*] (a mint resembling "yerbabuena" or *Mentha*, Puerto Rico)

southern fog-fruit (Florida) té [*cimarron, negro*] ([wild, black] tea); té de Yucatán [*del país*] (Yucatán [country] tea, Yucatán)

Linnaeus ([1753] 1957) had not seen living specimens of what he called *Verbena stoechadifolia*. Instead, he knew them from the reports of Charles Plumier from 1703, Sebastien Vailant in 1718 (1669–1722), and Adrian van Royen in 1740. Presumably all three earlier authors had studied the plants in cultivation in France and then in the Netherlands. It was 1803 when Andre Michaux discovered and named the second species as *Lippia lanceolata*. Both species have been moved from genus to genus as understanding of their relationships evolved. Most of us still do not know the differences between *Lippia* and *Phyla*, but the latter genus contains about 11 tropical and warm region species around the world (Mabberley 1997).

Little beyond the common names has been recorded for *Phyla*. The Mahuna of southern California used *P. lanceolata* to treat rheumatism (Moerman 1998). The Houma used *P. nodiflora* (*I'herbe à la tortue*, turtle herb) as a bath to make lazy babies walk (Speck 1941). Numerous other uses are recorded by Ayensu (1981) and Morton (1981) for that species. The reverence accorded *kabalyaxmik* by the Maya summarizes attitudes generally toward several species (cf. Arvigo and Balick 1993, Vasquez and Jacome 1997). *Phyla stoechadifolia* is endangered in Florida (Coile 2000).

One of the problems with attributing uses to *Phyla* is its confusion with related genera *Lippia* and *Aloysia*. Standley (1920–1926), for example, put them all in *Lippia*. Related *L. umbellata* is used as a remedy for colic. *Lippia dulcis* (*hierba duke*), is a well-known sweetener, and *L. graveolens* (*orégano*), better known as *A. graveolens*, is a spice used like the mint that is its namesake (*Oreganum*).

### *Phyllanthus*

(From Greek *phyllon*, leaf, and *anthos*, flower, because the flowers of some species are borne on leaflike dilated branches)

*Blattblume* (leaf flower, German)

*cherek hantu* (ghost's diarrhea plant; *P. frondosus*, Malay)

*dukong anak* (the child pick-a-back; *P. urinaria*, Malay)

*graines en has feuilles* (seeds below leaves, French Antilles)

*keezhu* (below, a reference to the fruits being borne under the leaves, Malayalam)

***Phyllanthus caroliniensis*.** From Britton and Brown 1897.

leaf-flower; *phyllanthe* (leaf flower, French) *quebra pedra* (stone breaker, Portuguese)

***Phyllanthus caroliniensis*** (of Carolina)

*cababesinixte* (a reference to a plant with small fruits that resemble ants; *cabal*, small, *bel*, clothes, *sinik*, ants, *te*, toward, *che'*, plant, Maya, Yucatán)

*canastilla* (little basket, Veracruz)

Carolina leaf-flower (a book name)

gale-of-wind

*[graines] en has feuilles* ([seeds] under the leaves, Martinique)

rock phyllanthus (a book name, Bahamas)

*yerba de la muina* (indisposition herb, Veracruz)

The first time I saw *Phyllanthus caroliniensis* in Florida was in the herb layer of a pinewoods that had recently burned. The plants were abundant for a year after the burn, and added a lacy green to the ground. Then, as other plants grew up, they disappeared. Soon afterward, the whole region became a housing development and those small herbs were gone. It all happened so fast that I never was able to learn much about these curious “leaf-flowers.”

*Phyllanthus* is a genus of about 800 species growing in the tropical and warm parts of the world (Mabberley 1997, Webster 2002). The genus ranges in life-form from large trees (e.g., *P. acidus*) to small herbs like *P. caroliniensis*. Linnaeus created the genus in 1753, although people had been using the word *Phyllanthus* for these plants long before then. The name was actually coined by Jan Commelin in 1697, and used by Catesby (1731–1732) and Albert Seba in 1734–1735. Linnaeus had adopted *Phyllanthus* beginning with *Hortus Cliffortianus* of 1738.

In *Species Plantarum*, Linnaeus recorded the six species that he then knew: *P. grandifolia*, *P. emblica*, *P. epiphyllanthus*, *P. maderaspatensis*, *P. niruri*, and *P. urinaria*.

Three species were based on specimens from India (*P. emblica*, *P. maderaspatensis*, *P. urinaria*), and the others from the Caribbean (*P. epiphyllanthus*, *P. grandifolia*, *P. niruri*).

It was not until Thomas Walter published his *Flora Caroliniana* in 1788 that *P. caroliniensis* became known. These small herbs have now been found from Pennsylvania to Missouri and Kansas south to Brazil, Bolivia, and Argentina (Fernald 1950, Hocking 1997). These herbs are like *P. niruri* and *P. urinaria* in aspect.

Vásquez and Jácome (1997) found people using *P. caroliniensis* to treat bronchitis, bruises, the heart, and skin problems. It is used as a diuretic in the French West Indies (Hocking 1997) and as a medicinal in Belize (Balick et al. 2000). The information available indicates that these herbs were used in the same ways as *P. niruri* and *P. urinaria*.

However, the story becomes more complicated once those other two species are considered. *Phyllanthus niruri* was described by Linnaeus in 1753. He thought it was from India and cited both Rheede's list of 1678–1703 containing plants used on the Malabar Coast of India and John Martyn's (1699–1768) list of plants in cultivation in London in 1728. Although Linnaeus's name continues in use, *P. niruri* has never been found in India (Webster 1955, 1956, 1970, 2002, personal communication 2003).

The native range of *P. niruri* is from southern Texas, through Mexico to Argentina (Stevens et al. 2001). The plants that are so famous for medicine in India are actually *P. fraternus*, not named until studied by Grady L. Webster (1955). Given the difficulty of identification of these small herbs, plus the prevalence of some widespread and weedy species, I suspect that the small native, and often rare, *P. caroliniensis*, has been relegated to a plant that is now neglected.

However, *P. caroliniensis* contains several bioactive compounds that would have made it useful. Phytosterols, quercetin, gallic acid ethyl ester, and geraniin have been identified in it by Cechinel Filho et al. (1996a,b). These authors wrote, "Pharmacological analysis also revealed that quercetin, gallic acid ethyl ester and a semi-purified fraction of flavonoids (1–100 mg kg<sup>-1</sup>, i.p.) exhibited graded and significant antinociception against acetic acid-induced abdominal constriction. The mean ID<sub>50</sub> values (mg kg<sup>-1</sup>) for these effects were: 18.8, 34.7 and 5.3, respectively. It is concluded that quercetin, gallic acid ethyl ester and some as yet unidentified flavonoids might account for the antinociceptive action reported for the HE [hydro alcoholic extract] of *P. caroliniensis*." Moreover, Santos et al. (1999) and Narayana et al. (2001) found that the bioflavonoids in *P. caroliniensis* were not only antinociceptive, but also anti-inflammatory.

The plant of choice in most, if not all, of the Americas is now *P. niruri*. However, Caribs in Dominica made a tea of the Old World exotic *P. tenellus* to induce abortions, and it kills rabbits and guinea pigs if they eat it (Hodge and Taylor 1957, Honychurch 1987).

In Cuba, *P. niruri* is known as *yerba de la niña* (little girl's herb). Elsewhere it is called *niruri* (Florida), *gale of wind* (Florida, English Antilles), *peronilla del pasto* (grass pear, Puerto Rico), *viernes santo* (Holy Wednesday, Puerto Rico, Colombia), *erva [herva] pombinha* (literally little dove herb, but slang for female genitals, Brazil).

There are two main themes in the common names—use to break up kidney stones and use as a quinine substitute. For the kidney stone theme, it is called *arranca pedras* [*arrebenta pedras*] (stone breaker, Brazil), *malva pedra* (probably a lapse for bad stones,

Brazil), and *quebra pedra* (stone breaker, Brazil). Names that allude to reducing fever are *feuilles la fièvre* (leaves for fever, Haiti), *quinina* (quinine, Haiti), *quinina Créole* (Creole quinine, Haiti), *quinina criolla* (Creole quinine, Dominican Republic), *quininina [quinine du] pays* (country quinine, Haiti), *quininito* (little quinine, Haiti), *quinino de pobre* (poor person's quinine, Puerto Rico), and *sulfate pays* (country sulfur, Haiti). In Paraguay, the herbs are *paraparaí mi* (from *parapa'rá*, Guaraní).

*Phyllanthus nirun* has names noting seeds below the leaves. Those include *des dos [de dou]* (from the back[s], Haiti), *derrière dos* (behind the back, Haiti), and *graines sur dos* (seeds on [the] back, Haiti).

In Cuba *P. niruri* is used to treat malarial fever, diabetes, liver problems, biliousness, and dysentery, and it is used as a diuretic. In Hispaniola, these bitter plants are used to treat malaria (Liogier 1978). In Brazil, the herbs are used against urinary disorders, diabetes, jaundice, and malaria (Mors et al. 2000). The fruit juice is considered antidiabetic.

*Phyllanthus* contain flavonoids, lignans, and glycosides (Mors et al. 2000). Given the confusion about the taxonomy, the identity of the species reported as *P. niruri* is dubious, but the genus is nonetheless chemically bioactive. Experiments show significant increase in diuresis and sodium and creatine excretion (Mors et al. 2000, Barros et al. 2003). In humans, persistent ingestion of tea from the roots expels kidney stones. *Phyllanthus* extracts show lipid-lowering activity (Khanna et al. 2002). There are also indications of antimalarial activity (Tona et al. 2001) and inhibition of HIV (Qian-Cutrone et al. 1996).

Over 30 years after I first saw *P. caroliniensis* in Florida, I learned that they were dispersed by mourning doves (*Zenaida macroura*). I had wondered for years how that region was able to support so many of these doves, and a partial answer came in a study by Tyler and Jenkins (1979). Doves are opportunistic and feed on an array of seeds—most of them small. The Oklahoma study found 17 species of plants in dove crops. So, the year of the burn in the pine flatwoods was also a good food year for the mourning doves. Now the few doves there are obliged to sustain themselves at feeders outside residents' homes.

### ***Physalis*: Ground Cherries**

(From classical Greek *physis* for a bladder, meaning the inflated calyx)

*Physalis walterii*. Drawn by  
P.N.Honychurch.

After spending years in Mexico, Francisco Ximénez published his book *Naturaleza y Virtudes de las plantas* (Nature and Virtues of Plants) in 1615. In that book was an herb called *coztomatl* (yellow tomato, Nahuatl). The herb is *Physalis* but no one is sure which of the species. The characteristic enlarged and inflated calyces growing over the tomato-like berry are obvious in the Ximénez drawings. Today we know and eat fruits of a Mexican species as *tomatillo* in *salsas*. In Ximénez's time, people in Europe were already familiar with their native *P. alkekengi* and some others from elsewhere.

Classical Greeks called the Old World plants *halikakabon* (bladder) or *phusalis*, and the Romans simply translated the Greek into Latin, *vesicaria*. Later people in southwestern Europe took their names from the Greeks, and said *halicacabon comun* (common bladder, French 1575) or *halicacabo uolgare* (common bladder, Italian 1551). This was also rendered *Boberellen* (bladders, German, 1536). The French sometimes said *couile bobes* (*bobe's* testicles, 1549).

By the mid-1500s, Europeans from Italy to Holland and Germany were familiar with plants now known as *P. alkekengi*. Each country had its own names for these plants. Many sources say the specific name, *alkekengi*, is an Arabic name. However, that does not appear to be correct. According to Pignatti (1982), "*alkekengi* corresponds probably to the *Halikakabos* of Dioscorides." This name was picked up because of the similar sound in the medieval Arabic *hab-kakeng e* and then, in the Italian dialects, it became *alchechengi*, *accatengi*, *arachengi*, *arcachenzi*, *chechingi*, *chichingi*, *chechingela*. Other popular names in Italy now are *coralli* (coral) and *palloncini* (balloons).

The name *alkekengi* was spread with the plants from southeastern Europe, and it also was spelled *alkakinge* (English, 1542), *akcakeng* (Turner [1548] 1965), *alquequanges* (French 1549), and *alkanges* (French 1551). Others compared the fruits to cherries,

calling them winter chirrir (1568), red winter cherries (1597), *Judenkirschen* (Jew's cherry, German, 1542), and *Schlutten* (ground cherry, German, 1542).

Some of the European names suggest that the plants were introduced comparatively recently. These allusions include *otra especie de yerua mora* (another species of blackberry herb, Spanish 1557), *baguenaudier* (comparison with the bladder mallow, *Colutea arborescens*, French, 1550), and *criecken van over zee* (foreign *criecken*, Dutch, 1549).

The plants came to northern Europe from the Middle East. That route is suggested by the German names *Judendocken* (Jew's bundle, 1542), and *Judenhutlin* (variant of *Judenhüttlein*, Jew's little hat, 1542). Those words are comparable with Jerusalem cherry still used in English. The name *rot Nachtschatten* (red night-shade or *Solanum*, 1542) may also indicate a comparison of a new plant with an old familiar one.

Nine species of *Physalis* are native to Florida (Wunderlin 1998). If indigenous Americans had as much trouble distinguishing the different types as botanists have, they probably considered them all the same. With little regard for species, plants are called by a number of generic common names. Those names include *alkekengi* [*alquequenje*] (USA, Puerto Rico), Barbados-gooseberry (USA, Europe), cherry tomato (New York), Chinese lantern (USA), ground-cherry (USA), husk-tomato (USA, Puerto Rico), Japanese lantern (USA), Jerusalem cherry (USA), strawberry tomato (USA in 1800s), *tomatillo* (Mexico), wild cherry (USA), and winter cherry (USA, Europe).

One of the most widespread species in Florida is *P. pubescens*. That plant was first reported in Brazil by Marggraf in 1648, with the indigenous name *camaru*. The species is still known there as *camapu* (from Tupi *kama'pu*). A synonym is *juá-poca* (from Tupi *yua'poca*, *yua'*, fruit). The only other South American name found for the species is *sousourouscorou* (Carib) or *pororu wokuru* (Carib, Suriname). However, in Yucatán, the Maya say *yooch ik bach* (*yooch*, animal food, *ik*, chile, *bach*, the chachalaca, *Or tails vetula*).

Many names refer to the inflated fruits. These include *bonnets de grandmaman* (grandma's bonnet, Louisiana), *coque-molle* (flabby shell, Hispaniola), *herbe a cloques* (blister herb, Hispaniola, Guadeloupe, Martinique), *maman laman* [*maman lanman*] (*maman*, mother, Haiti), *vejiga de perro* (dog bladder, Cuba), and *poc* (from French *pouche*, pouch, Guadeloupe, Martinique).

Several names note the impact *Physalis* has when either eaten or taken as medicine. These are *bate-testa* (hits the stomach, Brazil), *sacabuche* [*peludo*] ([hairy] stomach emptier, Puerto Rico), *coqueret de la Barbade* (Barbados flirt, French Antilles), *pantomima* (pantomime, Cuba), and *revienta caballos* (horse breaker, Cuba). Other names denote edibility or inedibility, as in *erva moura do peru* (Peru blackberry, Brazil), hairyground-cherry (USA), *tomate freadilla* (damaging tomato, Sonora), *tomatillo* (little tomato, Belize), and *yerba de sapo* (toad herb, Venezuela).

Joachim Camerarius recorded the foreign species *P. angulata* in European medical gardens in 1588. This species was known to African slaves when they arrived in the New World, and some brought their names with them. These words persist as *topo-topo* [*topotopo*] (Guyana, Trinidad), *topatop* (Jamaica), *topeton* (Panama), *tope-tope*, and *tophe-tophe* (Hispaniola). Variants are derived from the African Gold Coast, where the species is *totototo* or *tutotuto* (Twi), *wotowoto* (Ewe) or *gbato-gbato* (Ewe). Those names represent the sounds of children popping the inflated pods in play (Hutchinson and

Dalziel 1937) and are related to poppers (Bahamas) and pops (Barbados). The Barbadian name has been in use at least since 1750 (Hedrick 1919). In the Great Plains, Omaha-Ponca children called the fruits *pe igatush*, Pawnee children said *nikakitspak* (to pop, forehead), and both played a “popping” game similar to that of the Africans (Gilmore 1919).

Some names for *P. angulata* are allied with those for *P. pubescens*. Those referring to the fruit are *balãozinho* (little balloon, Brazil), *bucho-da-rã* (frog’s mouth, Brazil), *juá-da-capote* (hooded fruit, Brazil), *tomate* (tomato, Sonora), *tomate de cascara* (husk tomato, Sonora), and winter cherry (Trinidad, Jamaica). Others voicing their like or dislike are *sacabuche* (stomach emptier, Puerto Rico) and *matafome* (hunger-killer, Brazil).

Sometimes the Aztecs called this and other *Physalis* simply *tomatl*, now in Spanish *tomate* (tomato, Oaxaca). The plant we now call “tomato” (*Lycopersicon esculentum*) the Aztecs called *xitomatl* [*jítomatl*] (red tomato, Náhuatl). Spanish speakers in the New World generally call wild *Physalis* either *tomatillo* (little tomato) or *tomate del campo* (wild tomato).

The only species with a Seminole name is *P. walteri*, formerly known as *P. viscosa* (Sullivan 1985). While the Miccosukee call that species *lalilsatoklid:ki* [*fralilsatoklici:ki*, *falīcatoklitcigi*], Sturtevant (1955) made no comments. When Sheehan was among the Seminoles in 1919, he found them treating coughs and colds with the plants (von Reis and Lipp 1982). *Physalis walteri* was first recorded in Europe when Francisco Hernandez published his *Rerum Medicarum Nova Hispanae Theasurus* in Rome in 1651. He called this herb *miltomate* (wild tomato, Nahuatl, Oaxaca), although people in Belize use the name for *P. pubescens*. In Spanish, this is rendered *tomatillo de monte* (wild tomatillo, San Luis Potosí). The Huastec say *tuthay ch’ohool* (tomato herb, Huastec, Veracruz), *tut hay ts’ohool* (tomato herb, Huastec, San Luis Potosí), *its an t’ot* (tomato herb, Huastec, San Luis Potosí), or *tuthaayilan t’ot* (buzzard tomato, Huastec, San Luis Potosí). To the Zapotecs, it is either *bathus* (Oaxaca) or *bithus gihs* (wild *Physalis*, Oaxaca).

Other North Americans who use different species of *Physalis* are the Akimel O’odham, Apache, Cherokee, Dakota, Diegueño, Hualapai, Iroquois, Isleta, Keres, Meskwaki, Mohave, Navajo, Omaha-Ponca, Pawnee, Seri, Tarahumaras, Tohono O’odham, Winnebago, Yuma, and Zuni (Rea 1997, Moerman 1998, Hodgson 2001). All of these people ate the fruits and used the herbs as medicines (Yanovsky 1936, Curtin 1947, Felger and Moser 1985, Rea 1997, Moerman 1998, Yetman and Van Devender 2001). Some of the names they used for different species are *hanpok-hischasu* (owl eyes, Winnebago), *kekel viipid* (old man’s testicles, Akimel O’odham), *makan bashahon-shon* (crooked medicine, Omaha-Ponca), *tamanioli* (Dakota), *tombrisi* (Mayo), and *tulumisi* (Guarijío). The Seri recognize two they call *xtoozp* and *insáacaj*.

Fruits of most species are edible when ripe, either raw or cooked. They are fried, boiled, or stewed to make marmalade by cooking them with syrup. Leaves and green fruits are somewhat poisonous, as they are laxative and diuretic because of their solanine content (Morton 1981, Turner and Szczawinski 1991).

Species are often used indiscriminately as medicines (Lipp 1971, Hussey 1974, Wong 1976, Bye 1979, Coe and Anderson 1996). In the Bahamas, Cuba, Jamaica, Hispaniola, Colombia, Brazil, and Mexico, the fruits are considered febrifuge, and both leaves and fruits are used as diuretics. The leaves or sap are applied as emollient plasters, for

rheumatic ailments, or as drops for sore eyes in children. Leaf teas are taken to dispel indigestion, cure nephritis, cystitis, otitis, jaundice, herpes, and bowel problems called bich. Leaf suppositories are also used for bich, and the roots are used to treat toothache.

Some consider the genus narcotic and stimulant, at least partly because of its alkaloid, tannin, potassium chloride, and potassium citrate content. Berries contain acetylcholine, calystegines, ascorbic acid, and vitamin A (Zennie and Ogzewalla 1977, Morton 1981, Mello and Afiatpour 1985, Asano et al. 1995, 1997). Several species contain physalins, and the alkaloid hygrine is known from the roots (Willaman and Hui-Lin-Li 1970, Kawai et al. 2001). Withanolide glycosides have been found in *Physalis peruviana* (Sakurai et al. 1976, Lee et al. 1991, Ahmad et al. 1999), and the alkaloid 3- $\alpha$ -tigloyloxytropine is known from *P. alkekengi* (Yamaguchi and Nishimoto 1965).

Aqueous extract of leaves is antimicrobial (Ayensu 1981, Caceres et al. 1991). Other laboratory studies indicate possible use against gonorrhea (Caceres et al. 1995), cancer (Chiang et al. 1992a,b), and diabetes (Roman-R. et al. 1992). Modulation of the pituitary and basomedial hypothalamic lysyl-aminopeptidase activities has been shown in *P. alkekengi* (Vessal et al. 1996). Nutritional and quality analyses have been made of *tomatillos* (*P. ixocarpa*), and other species are presumably similar (Bock et al. 1995). Fruits are high in niacin (Morton 1981).

Two recent studies have been made of the relationships of the genus, one based on morphology (Alelius 1996) and the other on molecular genetics (Mione et al. 1994). The results are that *Physalis* may be paraphyletic, and *P. alkekengi* may not be closely related to the other species. The American *Physalis* seems to be most closely related to the endemic genera *Chamaesaracha* and *Margaranthus*. If that is true, then French botanist Joseph Pitton de Tournefort was correct when he segregated *Alkekengi* as a distinct genus in 1742.

### *Physocarpus*

(From the Greek *physis*, a pair of bellows, and *karpos*, fruit, a reference to the inflated carpels)

Linnaeus called these shrubs *Spiraea opulifolia* in 1753. He had studied living plants at the *Hortus Cliffortianus* and specimens sent by John Clayton from Virginia. They did not seem all that different from the other ten species of *Spiraea* that he described in *Species Plantarum*, and he saw no reason to separate them. However, Carl Johann Maximowicz, 1827–1891, studying them over a century later, decided they were distinctive. The fruits were inflated, unlike *Spiraea*, so he named it *Physocarpus*. There are now ten species known in the genus, which grows in North America and Asia (Mabberley 1997).

The best-known species in *Physocarpus* is the one in Florida, and it also grows from Virginia and West Virginia to Tennessee south to Alabama and Georgia. Ninebark barely extends into Florida, known only from Calhoun and Jackson Counties near Tallahassee (Wunderlin and Hansen 2002).

***Physocarpus opulifolium*.** From Britton and Brown 1897.

***Physocarpus opulifolius*** (powerful leaves, but probably a comparison with the leaves of *Viburnum opulus*)

*Blasenspiere* (bladder spit, German)

[common, eastern] ninebark (dating from 1796 or earlier when it was applied to *Spiraea*, and alluding to multiple bark layers)

Moerman (1998) listed three eastern tribes who used the plants. The Iroquois used ninebark as a gynecological aid. The Menomini made a bark drink to cleanse the woman's system and enhance fertility. The Ojibwa used the root as an emetic (King 1984). Tribes in the western states used it to treat gonorrhea and tuberculosis, and as a laxative (Foster and Duke 1990, Moerman 1998).

These plants are potentially toxic (Foster and Duke 1990). Presumably that toxicity is due to the cucurbitacins and triterpenes (Sarker et al. 1999, Kim et al. 2000).

### ***Phytolacca***

(Greek, *phyton*, a plant, and *lacca*, derived from Hindi, *lakh*, referring to a crimson dye)

***Phytolacca americana*.** a. Part of fleshy taproot, b. Upper branch with flowers and fruits, c. Flower, d. Upper surface of berry, e. Seed. From Buchholtz 1968.

***Phytolacca americana* (American)**

*amerikanische Scharlachberre* (American scarlet berry, German)

*bledo carbonero* (charcoal saltwort; also used for *Blutaparon*, which see)

cancer root (one of many plants with this name, Carolinas)

*chou-gras* (fat cabbage, Louisiana, fide Rafinesque)

*cokan* (northern tribes, fide Millspaugh 1892; Algonquian and cognate with *pakkan*)

*coskîlpâ* [*oskilpd*] (Creek; in Oklahoma, the word applies to *Sambucus*)

crow-berry (USA)

*dla:-ya-de* (Cherokee)

garget (the throat, originally from Old French *gargette*; the association is not clear)

*herbe de la laque* (lacquer herb, Quebec)

ink-berry (Carolinas)

*Kermesbeere* (scarlet berry, based on kermes or cochineal insects, German)

*koshe* [*kó:sî*, *ko:si*] (Mikasuki); *koshiba* (Choctaw); *koshibba* (Chickasaw); *kosiba* (Alabama); *kosabî* (Koasati); *os'a* [*osa*, *osá:*] (Creek, Muskogee)

*kox tippka* (Biloxi)

*morelle a grâppes* (bunch blackberry, Quebec)

*paok* (by Swedes in Pennsylvania in 1740s, fide Kalm [1753–1761] 1972; from an Algonquian word; cognate with *pakkan*)

pigeon [poke] berry (Carolinas)

poke salat (although “salat” and “salad,” are etymologically the same word, from Latin *salata*, they are not the same preparation; “salat” is made by boiled the young green leaves as a potherb)

[American] poke weed [pokeweed] (in use by 1751, USA); [Virginian] poke [skoke] (from Virginia Powhatan *pakkan*, based on Algonquian cognates meaning “blood”; in use by 1708; see also *Lithospermum*; OED 1971 incorrectly derived it from the Powhatan *uppówoc* or *apooke*, smoke, and cognate with the Narragansett *puck*, smoke)

*tabosso* (sometimes used for this plant, although also for sumac, *Rhus*, Alabama)

wild spinach (Carolinas)

Each spring when I was growing up, we went farther into the country to gather “poke” for greens. When just the first young leaves and stems came through the ground, we cut off the tops and took them home. After monotonous winter meals mostly lacking vegetables, those “greens” were a treat. We called the meal “poke salat.”

Anyone growing up in the eastern United States is likely to have eaten this spring potherb. The dish was shared by the Cherokee, Malecite, Iroquois, and Mohegans (Moerman 1998). Interestingly, the modern Alabama have noticed that “white people eat the young leaves,” but they do not (Sylestine et al. 1993). “Poke salat” is a dish of the young *Phytolacca* shoots and/or leaves eaten well cooked and with two changes of water. The potherb, however prepared, is somewhat laxative, and historically constituted an important addition of vitamins and minerals across the South (Morton 1968b, Nellis 1997).

The entire plant is poisonous when raw (Morton 1974, Foster and Duke 1990). Perhaps the first record of that was left by Mark Catesby (1731, 1:24). He wrote of the bird we now call the mourning dove (*Zenaida macroura*), “They feed much on the Berries of Poke, i.e., *Blitum Virginianum*, which are poison.” Common names crow-berry and pigeon berry also note that birds feed with impunity on the fruits.

Strained juice of ripe fruits may, however, be used to color food, when carefully separated from the poisonous seeds (Morton 1968b). Several groups used the red-purple fruits as dyes (Moerman 1998), and use in coloring is how the herb got its name.

The association of “poke” with *Phytolacca* dates from the first English colonists sent in the late 1500s by Sir Walter Raleigh to the Virginia coast. There they found Algonquian-speaking people referring to a number of plants as *pakkan*. That word became “puccoon” for *Lachnanthes*, *Lithospermum*, and *Sanguinaria*. The fourth one, *Phytolacca*, became “poke,” although based on the same root. The color is from the betacyan pigment caryophylline (Nellis 1997).

Juice of the berries was also used in coloring wines (Nellis 1997), but Porcher (1863) reported that practice was outlawed in Europe. He wrote, “The French and Portuguese mixed it with their wine, to give it color, and this was prohibited by royal ordinance of

Louis XIV, ‘on pain of death, as it injured the flavor!’” Juice was also made into ink. Porcher (1863) wrote, “With alum to fix the color, I have used the juice of the pokeberry as a red ink. The directions to the printer for this volume were written with this; before adding alum I found that the red color was fugitive. I consider it, prepared as above, an excellent substitute for carmine ink.”

The first records of Florida Glades people using *Phytolacca* were the pre-Columbian pollen samples studied by Hogan (1978). How Glades people used the plant is unknown, but they probably used it in the same ways as others in the United States. Yanovsky (1936), Sylestine et al. (1993), and Moerman (1998) recorded that the Alabama, Cherokee, Delaware, Iroquois, Mahuna, Micmac, Mohegan, Rappahannock, and Seminoles used the plants as medicine. More indigenous groups probably shared the custom.

Sturtevant (1955) found the Seminoles using the berries as an analgesic, especially for rheumatism. The Cherokee and Delaware used the berries exactly like the Seminoles, but the Iroquois and Rappahannock treated that problem with different preparations of the herbs (Hamel and Chiltoskey 1975, Moerman 1998). The Alabama still make a decoction of the leaves as an emetic and formerly used the berries in making a medicinal whiskey (Sylestine et al. 1993). Other tribes and European settlers used various plant parts as emetics, expectorants, cathartics, and poultices on sores (Porcher 1863, Millspaugh 1892, Foster and Duke 1990). Root tea from the herb was still in use to cure “ground itch” in the Panhandle when Murphee (1965) talked with people there.

Ingestion of seeds, leaves, or other parts is especially dangerous because of the toxins, although small quantities are not obviously immediately poisonous for most people (Lewis and Elvin-Lewis 1977, Foster and Duke 1990, Nellis 1997). Among the toxic chemicals are the alkaloid phytolaccin and the triterpene saponins phytolaccagenin and phytolaccatoxin. The latter is similar to cicutoxin of water hemlock (see *Cicuta*). Among the poisons are proteinaceous mitogens that produce blood cell abnormalities when ingested or absorbed through the skin (Foster and Duke 1990, Nellis 1997).

Many other species of *Phytolacca* are used, including the widespread *P. icosandra* (Morton 1981), for which the U.S. species was formerly confused. That plant is called by the Zapotec of Oaxaca, *biaa* or *piaa*, soap plant (Reko 1945). The chemical that led to use as soap also kills snails (Nellis 1997).

Howard (1984) found that older Seminoles in Oklahoma used the plant to predict the next growing season. He was told that, shortly before New Year, a person would go out to the *Phytolacca* patch and clean out the dead growth so that only the roots were left. On New Year’s Day, they returned to inspect the roots. If there were new young leaves, it meant a good growing season.

### *Picramnia*

(Named by Olaf Swartz with Greek *pikros*, bitter, *amnion*, the membrane around the fetus, in reference to the bark)

*Picramnia pentandra* (five anthers)

*aguedita* (little ague, ultimately derived from Latin [*febris*] *acutus*, referring to malaria, Cuba, Dominican Republic)

bitter-bush [root] (Bahamas, Puerto Rico)

*bois montagnes* [*moudongue, Madame*] ([lady] mountain bush, Guadeloupe, Martinique)

*bois poisson* (fish bush, Haiti, Guadeloupe); *bois sardine* (sardine bush, Haiti)

*café marrón* (wild coffee, Dominican Republic)

*fwenn* (possibly from *foin*, hay, Haiti)

*graines dorées* (golden grains, Guadeloupe)

*guarema* (probably Taino, Puerto Rico)

*hueso* (bone, Puerto Rico)

*ojo [palo] de peje [pez]* (fish eye [tree], Dominican Republic)

***Picramnia pentandra*.** (Left), a. Branch with pistillate inflorescences, b. Staminate flower, side view. c. Staminate flower, longitudinally dissected, d. Floral diagram of Staminate flower, e. Pistillate flower, side view. f. Pistillate flower, longitudinally dissected, g. Floral diagrams of pistillate flower. (Right), a. Branch with fruit, b. Serial buds in leaf axil. c. Leaf with opposite leaflets, d. Leaf with alternate leaflets, e. Fruits, complete and transversely dissected, showing variation in seed numbers.

*Drawn by Priscilla Fawcett. Correll  
and Correll 1982.*

*quina [quinina] de la tierra [del país]* (wild quinine, Cuba)  
snake-root [snake-stick, snake-wood] (Bahamas)  
*vaillant garçon* (strong waiter, Haiti)

Olaf Swartz gave us both the genus and species names for these trees in the late 1700s. He founded the genus on plants from Jamaica, and *P. pentandra* he discovered on Montserrat in the Lesser Antilles. Today the genus contains 45 species, all confined to tropical America (Mabberley 1997).

As suggested by the references to ague and quinine in the common names, this is a venerable remedy for fevers, malarial and otherwise (Roig 1945, Liogier 1974, Ayensu 1981, Morton 1981, Beauvoir et al. 2001). Throughout the Caribbean, the tree is used as a tonic and febrifuge (leaves, roots, bark), and against diarrhea. Roots are boiled with *Chiococca alba* and the decoction used to alleviate gas and menstrual cramps. That tea is used against colds and tuberculosis, and to increase the appetite (Roig 1945, Ayensu 1981). In Hispaniola, the wood is rarely used, but a red dye is extracted from the flowers (Liogier 1974). Haitians consider a decoction made from leaves and bark effective against fever, indigestion, dysentery, intestinal worms, and anorexia (Beauvoir et al. 2001). Caribs on Dominica soak the wood chips to make a bitter drink to alleviate appetite loss. Sap from the bark is put on lesions from yaws (framboesia) (Hodge and Taylor 1957). Among the Warao of Guyana, it is used to “bitter the blood” (Reinders 1993).

***Pilea***

(John Lindley named this with Latin *pileus*, cap or hat; he thought the sepals of pistillate flowers covering the achene resembled the “felt caps” used by Romans)

***Pilea microphylla*** (small-leaved)

*alfombra* (carpet, Venezuela)

artillery plant (from the way it “shoots” its seeds into nearby areas, Florida, Jamaica, Puerto Rico, Virgin Islands); *escopetilla* (little shotgun, Venezuela); gunpowder plant (was it really used in manufacturing powder? or is this another allusion to “shooting” its seeds?, England); kanonneer-plant (Dutch Antilles)

baby puzzle (Jamaica, Lesser Antilles); baby’s lace [lace plant] (Bahamas, Jamaica, Lesser Antilles, Belize)

*beldroega* (derived from Arabic *burd(u)lagá*, usually applied now to *Portulaca*, Brazil)

*botisuelo* (ground cover, Hispaniola)

*brilhantina* (shiny one, Brazil)

*dentelle [petite dentelles, tidentelles]* (little tooth [teeth], Hispaniola)

*doradilla* (little golden one, in reference to resemblance to a medicinal fern, Venezuela)  
*erva gorda* (fat herb, Brazil); *folha gorda* (fat leaf, Brazil)  
*erva mucuim* (worm herb, from *mukoo'i*, Tupi, Amazonas, Brazil)  
*frescura* (unkept, Cuba)  
 gale of wind (a comparison with *Phyllanthus*, which see, Florida)  
*golondrina* (swallow, Hispaniola)  
*ha'il tsan* (snake water, Huastec, San Luis Potosi)  
*hierba de la viruela* (measles weed); *hierba del tejado* (roof herb, from its growing there, Cuba)  
*madre per la [madreperla]* (mother-of-pearl, Puerto Rico); *madre selva [madreselva]* (mother of the forest, Puerto Rico)  
*mañanita* (little tomorrow, Cuba)  
*marposa* (probably a variant of "mariposa" butterfly)  
*palma del norte* (northern palm, El Salvador); *palmilla [palmita]* (Hispaniola)  
*panchita* (little belly, Hispaniola)  
*paragüita* (little umbrella)  
*parietaria* (wall weed)  
*[petit, ti] teigne [tengn] [blanche, plan]* (little [full, white] ringworm, Lesser Antilles)  
*pitsits wal* (scattered eyes, Huastec, San Luis Potosi)  
 rockweed (one of the most common places it grows is in rocky crevices)  
*samancito* (little useless one, Venezuela)  
*schaam-teloos*  
*señorita* (lady, Cuba)  
*sereno de invierno* (winter serenity, Hispaniola)  
 smoke plant  
*tumiin ts'ohool* (money plant, Huastec, San Luis Potosi)  
*urtiga* (comparing it to *Urtica*, Brazil)  
*verdolaguilla* (little purslane, Puerto Rico)  
 wild thyme [wild tim]  
*yedra [del tejado, de vidrio]* ([thatching, glass] ivy, Cuba, Puerto Rico)  
*yomha*  
*zizal-xiu [siisalxiw]* (*zizal* or *sisal*, *Agave sisalana*, *xiw*, herb, so called because it occurs frequently in the shade at the base of *Agave*, Maya, Yucatan)

Linnaeus called these plants *Parietaria microphylla* in 1759. At the time, European *Parietaria* was one of the few relatives that he knew, and he was inclined to include these tropical plants there rather than create a new genus. It was not until 1821 when John Lindley created the genus *Pilea*, and then in 1851 EM. Liebmann put the Linnaean species in it to create *Pilea microphylla*. Subsequently, about 200 species, from tropical and warm regions around the world, have been discovered (Mabberley 1997).

In the northeastern United States, the Iroquois and Cherokee have used *P. pumila* as a medicine (Moerman 1998). The more tropical *P. microphylla* has a much wider range and many more people have used it, although no records were found within the United States.

Roig (1945) recorded that Cubans use the plant as a refresher and against liver problems. He also noted local use as a diuretic, often used to treat inflammations of the urinary tract, as it is throughout much of its range (Meléndez 1989, Mors et al. 2001). The Huastec crush the plant and apply it to sores, itchy sores, and burns. They also treat sore eyes, mouth sores, *susto*, and fever in children with measles (Alcorn 1984). Brazilians not only use it as a diuretic, but also as an antithermic; poultices hasten maturation of boils (Mors et al. 2001). Other people use it to expel worms (Asian) and to treat wounds, female problems, inflammation, and tuberculosis.

### *Piloblephis*

(Rafmesque named these Florida near-endemics with Greek *pilos*, hair, and *blepharis*, an eyelid, so a “hairy eyelid,” in reference to the sepal pubescence)

***Piloblephis rigida*.** Drawn by  
P.N.Honnychurch.

***Piloblephis rigida*** (stiff, refers to the short leaves) (= *Satureja rigida*)  
*hapo:sikâ:yî* [*hapñçigaiyi*, *hapoosikaayi*] (simple term, Mikasuki);  
*haposhekaaye-choobe* (big *haposhekaaye*, Mikasuki)  
*kyfockv* [*kafôcka*] (simple term, Creek)  
 pennyroyal [pennyrile, penyryall] (dating from A.D. 500–600, derived  
 from Anglo-French *pulyole* ryle, Old French *puliol* real, and other

variants, ultimately from Latin *pulegium real*, royal thyme, or *Mentha pulegium*, Florida, Bahamas)  
 wild pennyroyal (mentioned by Williams [1837] 1962, Florida)

William Bartram ([1791] 1958) was the first to find these shrubby mints in Florida. However, it was not until 1834 when George Bentham officially created the name *Satureja rigida*, based on a suggestion by Bartram. It was under that name that the plants were discussed for many years, even though Rafinesque had put them in *Piloblephis* in 1838. Only since the 1980s has Rafinesque's name for them been adopted, and this seems to be the only species in the genus.

It was thought that these mints were endemic to Florida until they were found in the Grand Bahama region by the Corrells (1982). Presumably, those Bahamian plants are native and not introduced, but with the reputation "pennyroyal" has as medicine and food seasoning, that is problematical.

Well before Sturtevant (1955), the Creeks were known to have used *kafôcka*, particularly in what they call "Cow Creek Sickness." During his work with the Miccosukees on the Big Cypress Reservation, Sturtevant (1955) found them using this mint to treat "Hog Sickness" (periodic unconsciousness with shallow and slow breathing) and fever, and in medicines used at births, deaths, and during the busk (see *Pterocaulon*). An infusion also was used to treat sores and ulcers on the legs and feet. When used to treat these maladies, it was either mixed with several other plants or used alone, depending on the problem.

Alice Snow wrote: "My mother told us if you have a cold you could smell this. It was good smelling, so we would smell it all the time. *Kyfockv* is used in different treatments. Usually one or two sprigs of the leaves are needed" (Snow and Stans 2001). She still uses pennyroyal to treat congestion; boiling it and breathing the steam.

An important application has long been for flavoring food. *Hapo:sika:yi* is documented as having been added to soups (Sturtevant 1955), but probably to other dishes. Currently, the leaves are added to pots of turtle meat (Bennett 1997).

Morton (1968) recommended branches be used to make tea, but she did not mention that fresh is better than dried. Once the branches have dried, they lose some of their fragrance and taste.

### *Pinckneya*

(André Michaux named this genus after General Cotesworth Pinckney, 1746–1825, appointed as minister to France in 1796, but the revolutionary regime there refused him, cf. Taylor and Norman 2002)

***Pinckneya bracteata*.** From Sargent 1905.

***Pinckneya bracteata*** (having leaf-like structures in the inflorescence)  
fever-tree [fevertree] (Florida)  
Georgia bark tree (Georgia); bitter bark (Florida)

John and William Bartram found these plants near Fort Barrington in Georgia, and later William named the species *Bignonia bracteata* (Harper 1958). Andre Michaux did not realize that the plants he found on the St. Mary's River were the same, and published *Pinckneya pubens*. Rafinesque created the name now used in 1827. There are 17 species placed in the genus, with only 1 in the southeastern United States (Rogers 1987, Mabberley 1997).

Michaux originally recorded that the plant was “very useful in intermittent fever” in his *North American Sylva* of 1817–1818 (Porcher 1863, Taylor and Norman 2002). He learned that from either indigenous people or the Americans they had taught. The bitter bark, containing cinchonin, was used during the Civil War as a substitute for quinine in treating malaria (Millsbaugh 1892, Mabberley 1997). Porcher (1863) recorded, “Dr. Law, of Georgia, cured six out of seven cases with it. It did not distress the stomach.” Later he noted, “In Georgia a handful of the bark is boiled in a quart of water till the liquid is reduced to one-half; the infusion is given.”

### ***Pinguicula***

(From Latin *pinguiculus*, somewhat fat, referring to the viscid appearance of the upper leaf surface it uses to catch insects)

butterwort (name used from at least the time of John Gerarde's *Herball* of 1597, who wrote, “called Pinguicula, of the fatnes or fulnes of the leafe, or of fatening; ...it is called Butterwoorts, Butter roote, or white roote”)

earning grass (“earning” is a North Country British Isles word for cheese rennet)

*erba grassa* (fat herb, Italian); *Fettkraut* (fat herb, German); *grasilla* (little fat one, Spanish); *grassette* (little fat one, French); *measgran* (buttery, Gaelic)

*la:nihiliswâ* (lane, yellow, *heleswa*, medicine, Creek)

*mò than* (Gaelic)

*talakcihcayikî* (raw medicine, Mikasuki)

*tât-ort* (*tât*, to plug or stop up, *ort*, herb, Swedish); *tettegras* (*tette*, to plug or stop up, *gras*, herb, Norwegian)

***Pinguicula lutea*** (yellow, the flowers)

***Pinguicula pumila*** (dwarf)

Linnaeus had grown up with butterworts, which he knew as *tât-ort* (Linnaeus [1749] 1979). A few *Pinguicula* are circumboreal in acid bogs, and some grow south into Portugal and Italy. Butterworts were used to curdle milk. They were important medicines and were believed to avert evil in the British Isles (Beith 1995, Vickery 1995). Linnaeus (1753) knew only 4 species, but there are 46 in the Americas and Europe (Mabberley 1997).

Both Florida species have been used to treat “Raw Meat Sickness” (Sturtevant 1955). That malady stems from the belief that undercooked meat not only remains in the body, but “grows,” and causes abdominal pain. For mild problems the infusion is drunk cold, but if severe, the medicine is boiled.

## ***Pinus***

(Ancient Latin name for pines)

*ʔe'ksha* (Tunica)

*chooye* [co:yi] (Mikasuki); *choyyi* (Alabama); *coyyî* (Koasati), *cule* [*cûle*, *colî*] (Creek, Muskogee); *tiak* (Choctaw); *tiyak* [*tittiyak*] (pine tree, Chickasaw)

*furu* (Norwegian); *Föhre* (German)

*Keifer* (German); *keper* (Dutch)

*nohji* (Cherokee)

*ocote* (torch, from *ocotl*, Nahuatl)

*pin* (from Latin *pinus*, French); *pinho* (Portuguese); *pino* (Italian, Spanish)

*wazi* (Dakota)

***Pinus clausa*** (closed, meaning the partly serotinous cones)

***Pinus.*** *Pinus clausa* . *Pinus elliottii* .  
Both drawn by P.N. Honychurch.

*co:yihiskopóskî* [*tcoihickopocki*] (Mikasuki; cognate to Creek *cule*, pine, esse, leaf, *lopockuce*, little)

pitch pine (called “*P. rigida*,” which is not in Florida; the trees were “low, poor timbered tree, but produces turpentine and tar,” which seems best to describe this species, cf. Williams [1837] 1962)  
sand [scrub] pine

***Pinus echinata*** (spiny)

*ácuwe* [*etcuwe*’, *ícuwe*] (Catawba)

*choyyihissi hobaski* (*choyyi*, pine, *hissi*, hair [needle], *hobaski*, short, Alabama); *coyyí acakí* (*coyyí*, pine, *acakí*, dwarf, Koasati)

[long-tag, shortleaf, short-leaf, yellow] pine

*taklaha* (*tiak*, pine, *lakna*, yellow, Choctaw)

*teetpa hitcuwe*’ (chewed pine, the resin, Catawba; also applied to *P. palustris*)

***Pinus elliottii*** (commemorates Stephen Elliott, 1771–1830, professor in Charleston who published a flora of South Carolina and Georgia in the 1820s)

*chooye enlepaatooche*, *chooye ebeele* (pine branch tips, Mikasuki)

*chooye* [*co:yí*] (Mikasuki); *cule* [*colí*, *chulí*] (Creek); *tcuyi* (Alabama)

*cule emohlowakuce* (*cule*, pine, *em*, its, *elvce*, branch, Creek)

*este lopockuce* or *este-lopokecne* to (“where the little people live”; from *este*, person, *lopockuce*, small, *em*, its, *eto*, tree, Creek)

*nat’tsi* (Cherokee)

slash pine (Florida)

*yaat-hoboske emahe* (where the little people live, Mikasuki)

***Pinus glabra*** (smooth)  
spruce pine (Florida)

***Pinus palustris*** (of swamps, a misnomer)  
*atcuwe nu're* (pine fat [rich], Catawba); *an̄sudi'* [*ansûdi'*] (generic for pine or *P. palustris*, Biloxi); *an̄sudi'* *nitarixti* (Biloxi)

*choyyihissi hobaski* (*choyyi*, pine, *hissi*, hair [needle], *hobaski*, long, Alabama)

*choyyinaani* (*choyyi*, pine, *naani*, male, Alabama); *coyyi ná:ni* (*coyyi*, pine, *ná:ni*, male, Koasati)

longleaf pine (southeastern United States)

*ne'e mañ ne'e* (*ne'c*, tree, *mañ*, long, *ne'c*, tree, Atakapa)

*tiak fan̄ya* (*tiak*, pine, *fani*, squirrel, Choctaw); *tiak hobak* (*tiak*, pine, *holba*, resembling, Choctaw)

yellow pine (once the “principal timber, used for plank and scantling in the southern states; and also produces turpentine and tar,” Williams [1837] 1962; is this a translation of the Koasati *coyyilá:na*, *coyyi*, pine, *lá:na*, yellow?)

***Pinus serotina*** (late, alluding to the cones typically not opening until burned)

many cored pine (Williams [1837] 1962)

[marsh, pond] pine

***Pinus taeda*** (Latin for torch; ancient name for a resinous pine)

*choyyihoba* (*choyyi*, pine, *hoba*, castrated, Alabama)

*coyyi ná:ni* (*coyyi*, pine, *ná:ni*, male, Koasati)

loblolly pine (“has much sap,” Williams [1837] 1962)

oldfield pine (the plants quickly re-seed and sprout in old agricultural areas)

Pines are among the most widely used of plants throughout their range (Standley 1920–1926, Moerman 1998). Many pines have been employed in North American medicines, e.g., *Pinus palustris* and *P. rigida* have stimulant, laxative, diuretic, pectoral, vermifuge, discutient, antihyperpetic, detergent, baslastic, and vulnerary properties (Vogel 1970). Pine tar was in the U.S. Pharmacopoeia between 1820 and 1950 and has been in the National Formulary from 1950 to the present; it is considered an antibacterial, irritant, parasiticide, and expectorant.

The earliest records of pines being used in Florida were among the Glades people (Gilliland 1975, Hogan 1978, Austin 1980). Wood is the best-known product, although there are numerous other uses by people (Hamel and Chiltoskey 1975, Austin and Smith 1997). The inner bark and roasted seeds were eaten as famine food. Needles were cooked or eaten raw. Resin was an effective salve alone or as a medicine base, and teas from leaves were expectorants, antidiarrheics, and vermifuges. Lighter pine (the resinous heartwood) has long been used as fuel.

The Creeks used the wood for beams, ball poles, houses, torches, bighouse seats, baskets, and religious scarification (Swanton 1928a). The Seminoles continued those practices (Sturtevant 1955). In addition, the Seminoles formerly used the resin as arrow point glue and extracts of bark for tanning. When Sturtevant (1955) worked with the Miccosukee, they were using pines for “Ballgame Sickness” (caused by getting hit by a ball during the traditional single-pole game) and to treat rheumatism.

Snow and Stans (2001) note that the tips of branches are the best medicine. The Choctaw used them similarly (Taylor 1940). Four pieces, 4 inches long, are taken, crushed, and put in water with *vtakroluste* (dog fennel, *Eupatorium capillifolium*) and boiled. [Note: The multiple of four, an allusion to the cardinal points, is a reverential request for the aid of the spirits.] Sometimes the bark is used as medicine. The liquid is used to clean sores; for women’s medicine, a forked stem is used. Snow uses that branch in a medicine to prevent miscarriage.

### ***Piscidia*: Fish-Poison**

(From *piscis*, fish, and *caedo*, to kill or poison, Latin)

***Piscidia piscipula*. From Sargent 1905.**

I vividly recall the first time I ever saw a fishpoison tree (*Piscidia piscipula*) in flower in the spring of 1970. Not only was the tree impressive for the multitude of white, pink, and yellow legume blossoms, but it was literally alive with insects and birds. Standing in the Florida Keys on the edge of a road segment that had been abandoned in 1935 after the Labor Day Hurricane, I was able to distinguish at least ten kinds of bees. Moreover, I watched as birds from four families sipped nectar. There were ruby-throated hummingbirds (Trochilidae), several species of warblers (Emberizidae), spot-breasted orioles (Icteridae), and doves (Columbidae).

Europeans learned of these trees when British physician Hans Sloane returned from a tenure in Jamaica that began in 1687. In his book on the plants of that island, Sloane wrote *Coral arbor polyphylla non spinosa, fraxinis folia, siliqua, alls foliaceis exstantibus, rotae molendinariae fluviatilis, vel seminum laserpitii instar aucta* (Unarmed red tree with many leaves, leaves resembling ash, fruit pods with winged leaves standing out like windmill blades along rivers, or having seeds resembling carrots). That may not sound much like the plants we now call *Piscidia piscipula*, but the specimen in the

herbarium at the British Museum of Natural History in London confirms the identity. Furthermore, Sloane wrote, "The Indians and negros make use of this bark to take fish, especially in deep holes in inland rivers." Later, 57 years after Sloane's book was published, Linnaeus used its description and plate as the basis of the name *Erythrina piscipula* (little fish). Linnaeus was fooled by Sloane's reference to the flowers as "red," and he put the plants in the wrong genus.

Patrick Browne, however, knew the trees were distinctive and proposed the name *Ichthyomethia* (fish-wine, Greek) in 1756. Much later, Browne's name was rejected by international agreement and replaced by *Piscidia*. Charles Sprague Sargent gave us the modern name in 1891 when he made the combination *Piscidia piscipula*, and Rudd (1969) reinforced that placement. Unfortunately, some modern publications have not reached the 19th-century level; they retain the old synonym *Piscidia erythrina*. The incorrect name appears in many of the chemical records (Heller and Tamm 1975, Pietta and Zio 1983, Delle Monache et al. 1984, Redaelli and Santaniello 1984, Labbiento et al., 1986, Delia Loggia et al. 1988, Tahara et al. 1991, 1992, 1993a,b, Moriyama et al. 1992, 1993). Surveyors of the literature must be aware of this and similar nomenclatural complexities that may cause confusion.

Many of the common names, extending from the time of Hans Sloane in the late 1600s until today, allude to use of these trees to catch fish. To do that the bark and leaves are mashed and put in water. Some people simply say *Piscidia* is *barbasco* (fish poison), a Spanish word applied to a variety of plants, ranging from other trees in the Fabaceae to herbs in the Asteraceae. Others say *Piscidia* is *barbasco amarillo* (yellow fish poison, Colombia, Venezuela), alluding to the wood color to distinguish it from others called "*barbasco*." Wood in *P. piscipula* is heavy, hard, closegrained, and clear yellow-brown. It is more certain that the Huastec alternate name *k'anaw te'* (yellow maize tree, San Luis Potosí) is an allusion to the wood. There the wood is preferred for house posts; the heartwood is used to cure a variety of ailments, to divert evil eye in adults and even unborn children, and to ensure a long life (Alcorn 1984). There is a popular Mexican belief that the wood petrifies after many years, beginning with the heart. Perhaps that is why the heartwood is considered so potent in medicines. Other people note that the wood takes a fine polish and is durable in water, and therefore is used for boat building and piles of wharves. It has also been used as fuel, to make charcoal, and for cartwheels.

In the Lesser Antilles *Piscidia* is known as the *morta [á] poissons* (fish killer). Elsewhere it is the *colorin de peces* (red [flower] for fish, Guerrero, Michoacan), fish-fuddle (USA, Jamaica), fishpoison (Florida, Bahamas, Puerto Rico, Panama), or *matapez [mata-pescado, mata-peces]* (fish killer, Mexico, Colombia).

People used chemicals in the plants to stupefy fish and themselves. When a sedative was needed, extracts from *Piscidia* served the purpose, thus gaining it the names *borracho* (drunkard, Venezuela), *pah emborrachador* (intoxicating tree, Venezuela), and *bois [a] enivrer [énvirage]* (intoxicating tree, Martinique, Guadeloupe). The dry bark, especially from roots, has a strong odor of opium and tastes unpleasant (Standley 1920–1926). This bark produces burning in the mouth, and both odor and taste have resulted in the names *guamá [guaná] hedondida* (stinking *guamá*, a Taino word for several legumes, Cuba), and stinkwood [stink tree] (Virgin Islands, St. Eustatius, St. Martin). Mexicans said *cocuile [cocuite]* (*cococ*, pungent and *huítl*, herb, Náhuatl, Mexico) because of the taste. Maybe the name *cachimbo* (pipe, Costa Rica) is related. The names *pah de zope*

[*palo-zope*] (vulture tree, Guatemala), and *zopilocuave* (*zopihte*, vulture, from *zopilotl* or *tzopihtl*, and *cuave* from *uaxin* or *huaxin*, Nahuatl, El Salvador) more clearly refer to the odor and medical uses. The Aztec word *uaxin* [*guaje*, *huaje*, *huaxin*, *guaxi*] refers to both *Leucana esculenta* (Fabaceae) and *Crescentia cujete* (Bignoniaceae).

Other people simply view the trees, perhaps as I did when they were in flower, as a *candelón* (large candle, Cuba), *guamá candelón* (candle *guamá*, Cuba), and *guamá* [*guaná*] *de costa* (coastal *guamá*, Cuba). Those who say *flor de papagalh* (parrot's flower, Mexico) were surely noting the presence of those nectar-loving avians.

Alternatively, people may compare these trees with others. People call *Piscidia* the black mahoe (Trinidad, Tobago), dog (Jamaica), dogwood (Belize, St. Eustatius, St. Martin, Jamaica, Puerto Rico), black dogwood (Jamaica), Jamaica dogwood (Florida, Bahamas), *Jamaika hundsholz* (Jamaica dogwood, Dutch Antilles), or *frijolillo* (little bean, Mexico). Surely the name *chijol* (*chi-xo-lli*, swollen pod, Nahuatl, Tamaulipas, Veracruz) also refers to the legume fruits. Apparently, this Aztec name occurs in the Veracruz dialect of Huastec as *chiihol*, and among San Luis Potosi speakers as *ts'ijol* [*tzijol*], although Alcorn (1984) did not comment on the relationship.

Some of the names are either simple or obscure. These include *chaperno* (Guatemala), *haabi* [*habi*, *haabim*, *haabin*, *habim*, *jabin*, *jabine*, *jamcui*, *jamguij*, *javin*, *jebe*, *jubi*] (*ha*, water, *bin*, imperfect future form, or "that which will be green after the rains," Maya, Yucatan), may bush (Belize), *cahuirica* [*cahuinga*, *cahuiricua*] (Michoacan), *cuchivdn* (Venezuela), *tatzungo* [*taizungo*, *zatzumbo*] (Tarascan, Michoacan), *tiazab* [*tiaxib*] (Guatemala, Belize), and *tuncuy* (Mexico).

Several names clearly allude to medicines. Use against inflamed bowels is inherent in *colango naranja* (orange *colango* [from *col(e)*], derived from Greek *cholé*, *bile+angi(o)*, derived from Greek *aggeion*, vessel, Brazil). That same sense is inherent in *ventura* [*ventiera*] (for the belly, Puerto Rico). Since the chemicals are toxic, it is easy to see why the names *bois de chiens* (dog bush, French Antilles), *matapoijo* (louse killer), *pah de gusano* (worm tree, Belize), and worm-wood [wormwood] (Belize) are used.

There are seven species in *Piscidia* distributed throughout Central America, the West Indies, and northern South America. There are differing opinions on how these species should be circumscribed (Rudd 1969, Liogier 1974, Liogier and Martorell 1982). As now delimited, *P. piscipula* grows in southern Florida, the Bahamas, through the West Indies to Trinidad and Tobago, southern Mexico (Veracruz, Chiapas, Campeche, Yucatán, Quintana Roo), and through Central America to Panama and perhaps Colombia and Venezuela.

The bark contains compounds that are narcotic and analgesic. It has been used as an anodyne in neuralgia, nervous insomnia, and whooping cough (Standley 1920–1926, Goodding et al. 1965, Duke 1972). In addition, the bark extract has been used against toothache. Other uses include as a uterine depressant with low toxicity, a hypnotic, antispasmodic, diuretic, diaphoretic, and expectorant. In addition to applications to humans, it has been used to cure mange in dogs and as an insecticide.

Plants contain isoflavones (erythbigenin, erythgenin, jamaicin, junipegenin A, lisetin, piscigenin), saponins, piscidiasaponin, resin, rotenone and rotenoids, glycosides, piscidic acid, and the Neutral Bitter Principle piscidin, which is actually two compounds (Heller and Tamm 1975, Pietta and Zio 1983, Redaelli and Santaniello 1984, Labbiento et al. 1986, Delia Loggia et al. 1988, Tahara et al. 1991, 1992, 1993a,b, Moriyama et al. 1992,

1993, Hocking 1997). Laboratory studies indicate that the extracts are antifungal (Caceres et al. 1991), antiviral against poliovirus II, herpes, influenza, and vaccinia (May and Willuhn 1978), a uterine relaxant (Pilcher 1916, Butler and Mullen 1955), and a molluscicide (Dominguez and Alcorn 1985). Previous use as a sedative or analgesic also is supported by experiments (Delia Loggia et al. 1981, Pietta and Zio 1983). As poisonous as many of these compounds are, there are still insects that have been able to detoxify and consume them in *Piscidia* and the notoriously poisonous related genus *Lonchocarpus* (Cervantes 1999).

In a testament to Huastec attention to environmental interactions, they use the trees as predictors of the future. When the flowers dry up without setting fruit, farmers know that their *milpas* (corn fields) will fail that year (Alcorn 1984).

### ***Pisonia*: Devil's Claw**

(Commemorates the Dutch physician and pharmacist Willem [Wilhelm] Piso [Guillaume Le Pois], ca. 1611–1678)

My friend Barbara Hiaasen, who works at a Fort Lauderdale animal rescue center, once brought in a small plastic bag full of bird feathers. She said that a cedar waxwing (*Bombycilia cedrorum*) had been rescued with its feathers so full of these fruits that it could not fly. I pulled the mass of breast feathers and sticky fruits from the bag and examined them with a hand lens. They were devil's claw (*Pisonia aculeata*) fruits. It has long been known that the fruits of this scrambling bush endanger birds and Paul C. Standley, in his book *Trees and Shrubs of Mexico*, published in the 1920s, said that the "fruits stick to bird feathers so much that they cannot fly." Standley was a focused botanist, and for him to comment on birds getting stuck required unusual circumstances. That trait is not confined to this species; in Malaysia there is another called the "bird-catching tree" (Dalziel 1937).

These armed climbers have been known to Europeans since at least the late 1690s, when they were mentioned by Leonard Plukenet (1696). Indeed, he provided the first common name for the plants when he listed them as being *called fringeago* (Jamaica). That name remains today in the Bahamas as *fingrigo*, although no one seems to know its meaning or origin. Given the armed nature of the plants I cannot help wondering if that name is a version of *fin de gringo* (end of whites). The name more likely came from *fingerer* (thief), a word more commonly used in English in the 1500s and 1600s. Anyone who has ever been caught by these plants will understand that the claws on the stems steal bits of flesh, clothes, and other items from their victim.

*Pisonia aculeata* is known in southern Florida, the Bahamas, the West Indies, Mexico (Campeche, Chiapas, Oaxaca, Yucatán, Quintana Roo), Central America and South America through coastal Brazil to Paraguay and Bolivia. The same species occurs in Africa, Asia, and Australia, and that is the part of the range where it is perhaps not native. Morton (1981) attributed the devil's claw Asian and African range to human introduction, but that is uncertain.

Most of the common names for these nasty lianas refer to its armament. The names pull-and-haul-back, hold-back, pull-back, and pullback (Florida, Bahamas) date to the 1800s or earlier in Florida. Other names in English that note the curved, paired thorns on

the stems are black thorn (Barbados), cat's claw (Florida, British Antilles), cock spur (Bahamas), devilsclaws (Florida), prickly mampoo (Puerto Rico, Virgin Islands), tiger nail embra (Belize), and wait-a-bit (Florida, Bahamas).

In Spanish, the plant becomes a *bueno amigo* (good friend, Colombia), *cruceta espinuda* (little spiny cross, Oaxaca), *cruc espino* (spiny cross, Chiapas), *goma de uña [coma de uña]* (sticky claw, Tamaulipas), *uña de diablo* (devil's claw, Michoacan, Guerrero), *uña de gato* (cat claw, Tamaulipas, Michoacán, Guerrero, Cuba, Dominican Republic, Puerto Rico), *una de tigre* (jaguar claw), or simply *zarza* (spiny like *Rubus*, Cuba). To some people, these plants are a *caballero* (gentleman, El Salvador), probably derived from *cagadero [cargalera]* or *cagadero negro* (black *cagadero*). The word *cagadero* must be from an indigenous language because the similarly thorny *Celtis pallida* is *cagadero comestible* (edible *cagadero*, Nicaragua). Another comparison with that hackberry is *garabato* (iron hook, Durango, Sinaloa), and *garabato prieto* (black iron hook, Michoacan, Guerrero). They are also *tutum prieto* (black *tutum*, San Luis Potosí), maybe a comparison to *tutumushte* (El Salvador) or *tutumuste* (Guatemala), both references to tree *Ipomoea* (Standley 1922–1926).

French speakers say *P. aculeata* is an *amourette* (little lover, Guadeloupe, Martinique) or *croc à chien [croc de chien]* (dog's tooth, Haiti, Guadeloupe, Martinique). One of the names in Brazil suggests that it is the *espora de gallo* (rooster spur).

Indigenous languages convey the same ideas with *beeb [hbeeb]* (vine with spines, an interjection of surprise or pain upon encountering the spines, Maya, Yucatán), *huitzcocolótl [huiscalote, caltute]* (spiny, from *uitzcolotl*, Náhuatl, San Luis Potosí, Puebla; also applied to *Caesalpinia bonduc* in Cuba), *itsik' mitsu* (cat claw, Huastec, San Luis Potosí), and *mitz-matlayahuale* (*mitz*, you, *matlacautl*, pest, Nahuatl, San Luis Potosí). The last Nahuatl name apparently was taken to the Dominican Republic by the early Spanish where it became *mayacaule*. There are also simple and untranslated names like *istijdnuiya* (Totonac, Veracruz) and *loh [loj, lo]* (simple term, Huastec, San Luis Potosí).

My personal favorite among all these names is blaspheme-vine (Florida). Some of my students have provided their own invectives after getting inextricably caught by these plants.

Other people see the plants differently. Although I find nothing in the botanical literature about it having tuberous roots, it is called *espino y camote* (spine and tuber, Oaxaca, Chiapas) and *guechi-gu* (*guechi*, spine, *gu*, potato, Zapotec, Oaxaca). Those people were using those roots as laxatives (Standley 1920–1926), the universal cure-all.

Individual plants may climb for tens of meters over the surface of others or into nearby trees. Where they get so large, the scramblers form tangles of barbed stems that led Watt ([1889] 1972) to comment that they form “most excellent impenetrable fences.” Indigenous people also note those tendencies and call them *tapaciriba* (clothing the countryside, probably from *tapeçaria*, Brazil), *tampamolón [tampamalah]* (place covered with *loh*, Teenek, San Luis Potosí), and *yaguapendd* (from Tupí, *y a'warn*, ground, *pi'nima*, painted, Argentina).

Another name in Brazil is *cipó mole* (soft vine), presumably an allusion to the soft wood. The related *P. excelsa* of the Andaman Islands in Asia has such soft wood that elephants have been known to eat the branches with zest (Burkill 1966).

Devil's claw belongs to the family Nyctaginaceae, including more familiar plants like cultivated *Bougainvillea*, four-o'clock (*Mirabilis*), and the devil's bouquet or scarlet musk-flower (*Nyctaginea capitata*). Many members of that family have nocturnal blossoms. For its night-time flowers *P. aculeata* is called *huele de noche* (fragrant at night, Oaxaca, Guatemala).

Linnaeus gave us the genus *Pisonia* in 1753. The basis for that genus is *Pisonia aculeata*, called the "type species," or the permanent reference by which other species may be judged as related or not. In coining the name, Linnaeus honored Willem Piso who served the Dutch settlement in Bahia, Brazil with Georg Marggraf [Georgius Marcgravius]. Together they wrote one of the earliest books on medicinal plants of Brazil, the *Historia naturalis Brasiliae: De Medicina Brasiliensi* (book 4).

People throughout the Americas have used *P. aculeata* in a variety of ways. The branches formerly were made into barrel hoops in Jamaica (Standley 1920–1926). In Mexico, the plants are burned in *milpa* (corn field) preparation, the ash serving as a fertilizer (Alcorn 1984). Mostly, however, the plants have the reputation as medicines. Throughout its range, the root of *P. aculeata* is considered purgative, and decoctions or infusions of bark and leaves are used externally or internally against rheumatism, joint inflammation, and venereal disease (Standley 1922–1926, Roig 1945, Martinez 1969, Liogier 1974, Grime 1976, Mors 2001). The Mayas in Yucatan use it for urinary problems and to treat itch or mange (Martinez 1969, Morton 1981). The Huastecs in San Luis Potosi and Maya in Yucatan use the plants to treat boils and the ash mixed with lime and *nixtamal* water for other dermatological problems (Martinez 1969, Alcorn 1984). *Nixtamal* is the preparation of maize (*Zea mays*) kernels treated with the alkali in ashes to remove the outer coating prior to making the cornmeal for tortillas. Liquid from the raw stems and leaves is drunk to reduce fever.

No laboratory studies of *P. aculeata* have been found, but its Puerto Rican relative *P. borinquena* has shown 50% to 100% parasite suppression at 5 jig/ml of resistant malaria (*Plasmodium falciparum*), and 85% or more inhibition of microbial growth at 100  $\mu$ g/ml of tuberculosis bacteria (*Mycobacterium tuberculosis*) (Antoun et al. 2001). Another species, *Pisonia umbellifera*, contains six saponins, three of which are oleanolic acid saponins, and two of which have an unusual seco-glycopyranosyl moiety (Lavaud et al. 1996). Since other members of the family are known for diuretic and wound-healing activity, perhaps similar chemicals are in devil's claw (Lewis and Elvin-Lewis 1977).

Surely, the most famous medical relative of devil's claw is the four-o'clock (*Mirabilis jalapa*). That species contains a number of alkaloids such as trigonelline, saponins that make it soapy, and probably resins that make it a drastic purgative (Morton 1981). The plants are considered poisonous by most, and are now grown only for ornament. In Florida, however, the best-known relative of devil's claw is the *Bougainvillea*, cultivated in many yards and anywhere a beautiful, but armed, barrier is desirable. Anyone who has trimmed a *Bougainvillea* plant will relate to the common name of *P. aculeata*, "blaspheme vine."

***Pithecellobium*: Black Bead**

(From Greek *pithekos*, an ape or monkey, and *ellobion*, ear-ring, in reference to the unique coiled fruits)

British leader Oliver Cromwell's fleet took Jamaica from the Spanish in 1655, and 32 years later, in December 1687, Hans Sloane arrived on the island. Sloane, who was to become Britain's most prominent botanist of his century, lived and worked on Jamaica until his return to England in 1689. His herbarium specimen of plants we now call *Pithecellobium unguiscati* provides documentation for the first common

***Pithecellobium keyense*. Drawn by  
P.N.Honychurch.**

name—a necklace of its black seeds. The name “black bead” was already in use in the 1680s.

Both Leonard Plukenet (1642–1706) and his sometime rival Sloane simultaneously introduced black bead to England in 1696, although they called the tree an *Acacia* in their books. It was not until 1837 that Karl Friedrich Philipp von Martius (1794–1868), German botanist and professor in Munich, created the genus *Pithecellobium*. The “ape”

(*pithekos*) he saw eating the fruits was a New World monkey, probably a howler (*Alouatta* spp.).

Some names suggest other fanciful items. To people in Guadeloupe and Martinique the trees are *acacia a bracelets* (bracelet acacia) or *collier [à] diable* (devil's necklace). Other people note the leaves with *acacia à quatre feuilles* (four-leaf acacia, French Antilles), or the bark with *vainita de iguana* (iguana bark, Venezuela). People even think the curved fruits resemble horns and call the plant goatbush (Virgin Islands).

Several designations note the black seeds with their contrasting red arils. Among those names in English are beefsteak (Grenadines), black bead (Florida and Bahamas to Panama), black Jessie (Trinidad), bread-and-cheese (Virgin Islands, Barbados, Trinidad), mangrove bead tree (Barbados), and mangrove black bead (Barbados). In Spanish, they are *coralillo* (little red one), more of a reference to the aril than the seed. The Maya name *t'siu-che'* [*t'sin-che'*, *tsim-che'*, *tzin-che'*, *otsuiché*] (*t'siu*, red-eyed bird, *che'*, tree, Yucatan), notes a bird of the region (*Molothrus aeneus* or red-eyed cowbird), whose eyes resemble the red in the fruits. In Belize, it is *xa-coy* (*xa*, a word to introduce a question, *coy*, tranquil or serene, Maya).

One French name in the Lesser Antilles is a curiosity. It is either *tendre à caillou* (tender [thing] with pebbles) or *tendre à caillou-rivière* (tender [thing] with pebbles that grows by the river (Dominique, Martinique). Perhaps that is a reference to the edible aril. A German name is *Antillen kieselholz* (Antillean pebble-tree), but its allusion too is unclear, as the "generic" name for *Pithecellobium* is *Spiralhülse* (spiral bean) (Nikolov 1996).

A number of common names have other allusions. *Aromo* (perfume, Puerto Rico) presumably comments on the odor of the flowers, although I have never noticed much fragrance. *Cinazo* (ash-colored, Dominican Republic) could be another reference to the pinkish flowers. In Costa Rica, *P. saman* is known as *cenizero* (ashy one), so the names are related (Janzen 1982). Some think the trees look like privet (Jamaica), the temperate *Ligustrum* (Oleaceae). People in northwestern Mexico say *guamuchilillo* (Sonora) because it is a small version of *guamúchil* (*Pithecellobium dulce*).

There are also several names apparently in indigenous languages that have not all been identified or translated. These names include *dinde* (Colombia), *guichere* (Venezuela), *orore* (Cumanagota, Cariban, Venezuela), *pidua* (Chocó), and *yacure* (Arawak?, Venezuela). In Barbados, the tree is moabite. However, any relationship between the plant and the people of Moab, a region that bordered on the territories of the trans-Jordanic Israelites in the 1380s or earlier, seems unlikely.

By far the most common allusions are to the plant's armament. The best-known English names mentioning the thorns are cat's claw [catclaw] (Florida, Puerto Rico), catclaw blackbead (Florida), crab prickly (Virgin Islands), and crab wood (Dutch Antilles). Other languages render these *uña de gato* (cat claw, Cuba, Dominican Republic, Puerto Rico, Nicaragua, Panama), *uña de gatú* (cat claw, Dutch Antilles), *griffe-chatte* (cat's claw, Dominique, Martinique), or *bois crabbe* (crabwood, French Antilles).

People have some wonderfully obtuse ways of cursing these plants. They may be the *arranca pellejo* (skin puller, Venezuela), the *beshi di Juana* (Jane's kiss, Dutch Antilles), *bois trainant* (dragging tree, Dominique, Martinique), *manca montero* (wild impediment, Cuba), *rolón* (enveloper, Puerto Rico), or the *rolon escambrón* (scaly enveloper, Puerto

Rico). To others, they are *avaramo* (Brazil) because they resemble the *avard* or *Arecastrum* palm, both notably spiny. They might be *escambrón Colorado* (big red scale), *espino de mar* (sea spine), *espino de playa* (beach spine, Nicaragua), or the *espinuelo* (spiny one, Venezuela). Nevertheless, everyone's view after being caught in the claws and branches of this plant is that it is the *diaballe* (devil, Martinique).

Linnaeus ([1753] 1957) captured the bristly nature of the tree when he called it *Mimosa unguis-cati* (cat's claw mimosa). He knew the plants from the botanical garden in Uppsala, Sweden, and from Sloane's Jamaican herbarium specimen. However, the species ranges from southern Florida, through the Bahamas, the West Indies, and Mexico (Tamaulipas and Sinaloa) south through Central America to Bonaire and Curaçao, Venezuela, and Guyana. Throughout its range, everyone has used the plants. The wood is clear brown, hard, and heavy, and has been used by all who know it, especially in construction (Morton 1981). The fruit yields a yellow dye.

The Spaniards apparently thought that the black seeds resembled the kidneys and the immature white aril the fat surrounding them. Therefore, by the Doctrine of Signatures, they concluded that the plant was good to treat kidney problems. Some think the Spaniards started using the bark and fruits to treat kidney problems, but people who preceded them in the Americas had used the plants long before Europeans arrived. Since the bark and fruit are rich in tannin and astringent, they had been used to treat bronchitis, chronic diarrhea, and hemorrhaging for generations (Standley 1920–1926, Roig 1945, Mors et al. 2001). The bark was also considered tonic and diuretic and was used to treat fever, and to cure chronic sores. During early European history the plant in Jamaica was considered the “sovereign medicine for the stone and gravel,” and also for the liver and spleen (Standley 1920–1926). In Curaçao the leaf decoction is taken to relieve colds (Morton 1981).

The related species, *P. keyense* (of the Keys), is similarly rich in tannins, and is used to stop bleeding. In the Bahama Islands, leafy twigs are chewed or made into a “tea” to stop bleeding 3 or 4 months into pregnancy (Morton 1981). That species, easily confused with *P. unguis-cati*, is also known as black bead (Florida, Bahamas), ram's horn (Bahamas), or aroma (Bahamas).

People consider the aril edible, but some are sweet and others are astringent. Perhaps if they are eaten while still white they would be tastier, but those I have tried were red, in fully open fruits, and tasted too much like alum. Seeds are still strung into necklaces and rosaries as they were in Sloane's time.

The most famous member of the genus is the American *P. dulce*. That species is most often known under some variation of the Náhuatl name *quauhmoçitl* (snake jaws), including *huamúchil*, *cuamuchil*, *guamúchil*, *quamochitl*, *guamuche*, *camanchil*, *camonsil*, and *camachile*. While the plant was first recorded by Hernández in 1651, the connection between the name and the plants carried around the world by the Spanish remained unknown for centuries. Indeed, the vagaries of where a plant is first collected and reported as new to science are unpredictable. *Pithecellobium dulce* was described in 1795 from the Coast of Coromandel in India, and for decades people thought it was native to the Old World. Then it was discovered that it had been taken there by the Spanish, first to the Philippines, and then to mainland Asia (Standley 1920–1926).

Since no chemical studies have been found for *P. unguis-cati* or *P. keyense*, the best that can be done is to compare it with congeners. *Pithecellobium dulce* contains tannins

(Steynberg and Hemingway 1994), triterpene glycosides (Yoshikawa et al. 1997, Nigam et al. 1997), triterpene saponins (Sahu and Mahato 1994), and vernolic, malvalic, and sterculic acids (Hosamani 1995). An Indonesian species contains flavan-3-ol gallates and proanthocyanidins (Lee et al. 1992). Triterpene saponins are anti-inflammatory (Sahu and Mahato 1994), triterpenoid glycosides are antifungal (Khan et al. 1997), and other compounds are antimicrobial (Ali et al. 2001). Related species *P. saman* and *P. mangense* yield gum exudates (Leon De Pinto et al. 1995), and *P. saman* contains saponins similar to those in *P. dulce* (Varshney et al. 1985).

*Pithecellobium flexicaule* produces seeds that are consumed in northeastern Mexico (Alanis Guzman et al. 1998) and that have been used in afforestation in Texas (Vora and Labus 1988). Related species have uses like *P. unguis-cati* and maybe similar chemicals.

Sometimes Florida common names are specific: *P. keyense* is blackbead and *P. unguis-cati* is catclaw. Nowhere else in their range are they distinguished, and botanists did not even separate the two until *P. keyense* was described in 1928. However, a small gall-wasp (*Tanaostigmodes pithecellobiae*) uses only *P. keyense* and ignores *P. unguis-cati* (Weekley 2000). Once again, insects are better biologists than humans.

### *Pityopsis*

(Thomas Nuttall named this Greek *pitys*, pine, and *opsis*, resembling)

*Pityopsis graminifolia*. Polyploid varieties, a. *Pityopsis* var. *latifolia*; habit of a robust plant, b to e. *Pityopsis*

var. *tracyi*. b. Habit, c. Head; only some florets drawn; the heads of var. *latifolia* are smaller, d. Mid-series phyllary; chlorophyllous zone dark. e. Mature cypsela with disk floret attached. *Drawn by John C. Semple*. Modified from Semple and Bowers 1985.

- Pityopsis graminifolia*** (with leaves like grass)  
fever grass (Florida Panhandle)  
golden aster (Florida)  
gopher grass (Florida Panhandle)  
[silk, silver]-grass (reference to the white pubescence on the stems and leaves)  
*nashoba impisa* (*nashoba*, wolf, *im*, its, *pisa*, eyes, Choctaw)  
*pahátlo:ci* (white-black grass, Mikasuki)  
*pake hatkooche* (small white grass, Mikasuki)  
*paho:catli* (Mikasuki)  
*pvhe hvtku* [*pvhke hvtku*] (*pvhe*, grass, *hvtke*, white, *oce*, small, Creek)  
*solopí ahissi* (*solopí*, ghost, *ahissi*, medicine, Koasati)  
scurvy-grass (a use not recorded elsewhere)

The genus *Pityopsis* comprises eight species ranging from Canada to northern Mexico (Semple et al. 1980, Semple and Bowers 1987). In the southeastern United States there are records of use among several native groups. Indigenous people in the coastal Carolinas used the plant as a poultice for sprains (Morton 1974). Now people in the Carolinas make a tea of fresh leaves before the plants flower to treat kidney and bladder problems. The tea is considered a good diuretic to relieve dropsy (edema).

The Choctaw use burned plant ashes to treat mouth sores (Bushnell 1909). The Creeks used a mixture of plants including *Pityopsis* to reduce fever (Spoehr 1939 in Sturtevant 1955). The Seminoles on the Big Cypress Reservation were using an infusion of the plants for colds and fevers when Sturtevant (1955) worked with them. He also recorded that they used the plant for “Cow Creek Sickness,” in childbirth and in the busk (see *Pterocaulon*). Modern Seminole Alice Snow recorded that the plant is used to treat headache but gave no further information (Snow and Stans 2001).

Sturtevant (1955) was told about a plant called *pahátlo:ci* (white-black grass, Mikasuki). He had no voucher and did not know its identity. Based on the uses and other information he gave about that plant, it might have been *P. graminifolia*. Murphee (1965) found residents of the Panhandle continuing the use of “gopher grass” to treat boils and infected cuts, fevers, gout, ground itch, and rheumatism.

*Plantago*

(Linnaeus continued the Latin *planta*, footprint or sole of the foot, *ago* from *agere*, to bear or resemble, following use by Pliny, A.D. 23–79)

*cuach Phàdruig* (*cuach*, drinking cup, *Phàdruig*, of Father Druid, for *P. major*, Gaelic)

*groblad* (healing leaf, for *P. major*, Norwegian)

*kjempe* (giant, Norwegian); *koempe* (translated “warrior” by Coffey 1993; supposedly called that because of a game in which children try to knock the “heads” off each other’s “weapons,” which are the flower stalks; generic for genus, Danish)

***Plant ago, comparing alien and native species.***

1. *Plant ago lanceolata*. a.

Flower, b. Capsule, c. Seeds. 2.

*Plantago major*. a. Flower, b. Capsule,

c. Seeds. 3. *Plantago rugelii*. a.

Flower. b. Capsule, c. Seeds. Drawn

by Regina O. Hughes. From Reed

1971.

*llantén* [*yantén*] (the broad one, from Latin *planos*, Spanish)  
 plantain (from Latin *plantagenim*, sole of foot, in reference to the large broad leaves; first used in English about A.D. 1255); *piantaggine* (Italian); *plantain* (French)

*slàn lus* (healthy herb, Gaelic)

waybread [*waybred*] (from Old English *waybráde*, meaning “broad-leaved plant growing beside the way”); *vejbred* (waybread, Danish); *weegbree* (Dutch, from Middle Low German, *wegebrede*); *Wegebreite* (German, from Old High German *wegbrieta*); *Wegerich* (of roads, German)

white-man’s footprint (“New England Indians,” tribe not specified, cf. Millspaugh 1892)

***Plantago aristata*** (bearing bristles)

buckthorn [buckhorn plantain] (from Latin *cervi spina*; applied by Valerius Cordus, 15147–1544 to *Rhamnus catharticus*’, later applied to other genera)

[bottlebrush, bracted, large-bract, largebract] plantain (the modifiers refer to the inflorescence)

ribwort (an allusion to the prominent veins in the leaves; originally applied to the European *P. lanceolata* about A.D. 1440; later expanded to the American species)

***Plantago rugelii*** (named for its discoverer Ferdinand Rugel, 1806–1879, German-born planter and explorer in the southeastern United States)

[blackseed, common, Rugel’s] plantain

***Plantago virginica*** (of Virginia)

*bo-u-na* (Kiowa)

[dwarf, hoary, pale-seed] plantain

It has always struck me as odd that temperate and tropical plants (*Musa*, *Plantago*) are both called “plantain.” Apparently, I have not been alone in that reaction, as it was discussed by Father Acosta in 1590 and numerous authors since (de Candolle [1886] 1959, OED 1971). Current opinion suggests that the *Musa*, named “plantain” or *plátano* in Spanish, came from Latin *platanus*, referring to the broad leaves. The original comparison was not to the temperate deciduous tree, but simply a reference to wide leaves (see also *Platanus*). In Portuguese, *plátano* still means *Platanus*, even in Brazil where *Musa* is *banana*.

A dictionary of Galibi published in 1664 glosses *Musa aspalatana*, and a Carib dictionary of 1665 says they were known as ‘*balátana*. In Tupi, they were *prátane* (OED 1971). De Candolle ([1886] 1959) suggested that those words were derived from *bala* or *palan* from Malabar and introduced by the early Portuguese. The Brazilian Tupi now is *pacoba* or *bacoba*, while in French Guiana it is *bacove* (both from Tupi *pa* ‘kowa, leaf for wrapping). Regardless of how the name for *Musa* was derived, it is clear that the name for *Plantago* came from the Old Latin name for the temperate plants.

It probably is impossible now to separate what indigenous people did with *Plantago* from uses they learned from European settlers. The plantain had long been used in medicines in Europe, and it figured prominently in the writings of Pliny (A.D. 23–79), Dioscorides (A.D. 40–80), and Galen (A.D. 129–7200). Two species were discussed by Leonard Fuchs in 1542, William Turner in 1568, and John Gerarde in 1597, among others. During this time period, *P. major*, the best-known species, was called weybrede or plantayne by Turner, while in German it was *Wegrich* (orthographic variant of *Wegerich*), in Dutch *wechbree* (orthographic variant of *weegbree*), in Italian *piantagine*, and in Spanish *llantén*. Then, as when discussed by Millsbaugh (1892), it was largely considered vulnerary and demulcent, and recommended for coughs and bronchial problems.

*Plantago aristata* was used by the Cherokee to treat headache, dysentery, poisonous bites and stings, burns, and sore eyes, and in a douche (Hamel and Chiltoskey 1987). The Kawaiisu and Mendocino also used it in the western United States (Moerman 1998). The Menomini used *P. rugelii* as a dressing on burns or to treat inflammation (King 1984).

Possibly a formerly more widespread view of these plants was recorded by Vestal and Schultes (1939). They found that the Kiowa regarded *P. virginica* as a symbolic plant. Old men tied garlands or wreaths around their heads during dances as a symbol of health.

### *Platanthera*

(Louis Claude Marie Richard created the name from Greek *platys*, broad, *anthem*, anther)

*Platanthera ciliaris* (fringed, the petals)

orange-plume

*Waldhyazinthe* (forest hyacinth, German)

yellow finger orchid; yellow fringed orchid [orchis]

When I was growing up, I learned from watching to spit on the baited hook before beginning fishing. The practice always struck me as odd, but many of the older fishermen did it routinely. I never knew if it was part of my Gaelic or Cherokee ancestry.

Then I learned that the Cherokee used roots of the yellow-fringed orchid on hooks to make fish bite (Hamel and Chiltoskey 1975). Members of that tribe have not always used the orchid, but they formerly used the Venus fly-trap (*Dionaea muscipula*). Mooney's (1885–1886) paper included the following prayer for catching fish by his Cherokee informant *A'yuninis*, whom he called Swimmer: "Listen! Now you settlements have drawn near to harken. Where you have gathered in the foam you are moving about as one. You Blue Cat and the others, I have come to offer you freely the white food. Let the paths from every direction recognize each other. Our spittle shall be in agreement. Let your and my spittle be together as we go about. The fish have become a prey and there shall be no loneliness. Your spittle has become agreeable. I am called *A'yuninis*. Yu!"

The Cherokee took a cold infusion of the orchid to stop headache and diarrhea (Hamel and Chiltoskey 1975). The Seminoles used the roots in a remedy to treat snakebite (Sturtevant 1955).

*Platanus*

(The original Greek, *platanos*, broad, in reference to the leaves, a name for the plane-tree used by Pliny, A.D. 23–79; the Greek Theophrastus, 370–288 B.C., spelled it *platys*)

*Platanus Occidentalis*. a. Branch with fruit, b. Achene.

c. Trichome. *Drawn by Vivian Frazier.*  
From Correll and Correll 1972.

*Platanus occidentalis* (western, i.e., of the Western Hemisphere)  
*akhatka* (*oke*, water, *hatka*, white, Alabama); *akhv'tkv* [*akhatkv*] (*owv*, water, *hvtke*, white, Muskogee)

*álamo* [*álama blanco*] (usually used for *Populus*, Tamaulipas, Nuevo León, San Luis Potosi, Veracruz)

American plane [plane-tree, planetree] (to distinguish it from the European plane tree, *P. orientalis*, Canada, USA); plane [plane-tree, planetree] (from Old French *plasne*, in turn from *planus*, broad, because of the broad leaves, used in English by 1382; perhaps originally applied to *Acer pseudoplatanus*); *Platane* (German); *platane* (Quebec, France); *platano* (Italian); *platano occidental* [*occidentale*, *de Virginia*] (western [Virginia] plane-tree, Canada, USA); *westerse plataan* (western plane-tree, Dutch, Canada, USA, West Indies)

*aya* (Veracruz)

*ayan' sanhan' udi'* (“strong wood tree” or *san*, white?, Biloxi; compare with Omaha *jan san*, white wood and Osage *sansan*, white sycamore)

*bois puant* (stinking tree, Canada, France)

butterwood (a corruption of “button”?, North America); buttonball[-tree] (USA); buttonwood (surely an allusion to the round, buttonlike fruits; recorded in Swedish by Kalm in 1753; first published in English by Frederick Pursh in 1814 for this species, Canada, United Kingdom)

*ciṭó* (Koasati); *sini* (Choctaw)

*cotonier* (cotton tree, French, USA)

*keisewaquata* (Shawnee, fide Edgar 1891)

*kuwajunega* (Cherokee)

*oo-da-te-cha-wunnes* (big stockings, Delaware?, USA)

[American] sycamore tree [sycamore] ("sycamore" was originally applied to *Ficus sycamorus*, a fig in Egypt, Syria, and nearby countries. The word is a combination of Greek *sykos*, fig, and *mows*, the mulberry, and came into English about A.D. 1300. By ca. 1588, it was applied to European *Acer pseudoplatanus*, and then to American *Platanus* by 1814 or perhaps before.)

Virginia maple (name in New England in the 1740s, fide Kalm 1753)

*wasbok* [*watenbok*] (water beech, used by Swedes in Pennsylvania in the 1740s, Kalm 1753); water beech [waterbeech] (published in Swedish by Peter Kalm in 1753; the OED says first in English by Frederick Pursh in 1814)

*yap hi-tuwi* ' (tree of burrs); *yap taktce' hi'tcuwi-'hare* [*ya bwe*] (tree white [of] many burrs, Catawba)

The common names "plane-tree" and "sycamore" have been confused in English since the 1300s. That confusion reflects the application of the names to *Acer pseudoplatanus* and *Platanus orientalis*. For example, Vickery (1993) devotes almost two pages to the "sycamore" (*Acer*), yet that maple in Norway is the tanbark plane (*platanlonn*). In the United States, a "sycamore" is *Platanus*.

The name "plane" was in English before the "official" introduction of *Platanus*. In 1398, a John De Trevisa wrote, "The plane is a colde tre and a drye, and ye leaves therof helep in hoot eveles." Therefore, by that period, Europeans as far north as England were making medical use of a "plane" tree that must have been *Acer*.

William Turner's *Herball* recorded that *P. orientalis*, a native to Asia Minor, was introduced into Britain around 1562 (OED 1971). Then, 78 years later, John Parkinson told us that John Tradescant had *P. occidentalis* sent to him from Virginia and introduced it into England. Neither of these two species did well in the British Isles. In 1675, people noticed a different plane-tree. Although these hybrid trees (*P. xacerifolia*) are now called the "London Plane," they probably originated in France or Spain (Edlin and Mitchell 1985). From that point, the "plane" became one of the most common street trees in England and much of the rest of Great Britain.

The Cherokee were one of the few tribes recorded as using the wood of *Platanus* (Hamel and Chiltoskey 1975). Settlers used the wood for crates, interior finishing, furniture, cooperage, rollers, butcher blocks, and tobacco boxes (Vines 1977). In spite of this usage, the technical sheet from the U.S. Forestry Service is not overly complimentary. It states that, although the wood is not durable, "It holds its shape well after steaming and machines, but requires high speed cutter heads to prevent chipping. It shrinks moderately in moderate in weight, hardness, stiffness, shock resisdrying and is inclined to warp when flat sawn." The sapwood is white to light yellow, while the heartwood tance, strength in bending, endwise compression, and is light to dark brown. Sycamore is classified as nail-holding ability. It has a close texture, glues well, and resists

splitting due to interlocked grain. The Forestry Service noted modern application in furniture (especially drawer sides), containers, millwork, flooring, veneer, pallets, boxes, plywood, pulp wood, paper, and particle boards.

Although there seem to be no medical applications of *Platanus* in Europe, indigenous Americans used it throughout its range. The Cherokee considered the trees, but especially the bark, cathartic and emetic, and used it for menstrual and urinary problems and measles. They also treated dysentery with an inner and Chiltoskey 1975, Moerman 1998). The Creeks, bark infusion. Externally, the Cherokee and Iroquois used sycamore in a steam bath for rheumatism (Hamel Delaware, and Meskwaki treated colds, sore throat, infusions to treat skin eruptions, scabs, eczema, and hoarseness, and tuberculosis with the bark. The Cherokee, Iroquois, and Meskwaki used bark or root knife and ax wounds (Swanton 1928a, Taylor 1940, Hamel and Chiltoskey 1975, Moerman 1998). Moerman (1998) recorded Mahuna use of this species, but this tree does not grow there (Hickman 1993).

Foster and Duke (1990) found that the bark was once recommended by descendants of Europeans for rheumatism and scurvy. They found no evidence of efficacy. Lewis and Elvin-Lewis (1977) mention only that the airborne pollen causes allergies. Hocking (1997) affirms that the leaves were formerly used in eye lotions, and that the plant yielded antipyretic tonics. He further notes that it, like *P. orientalis*, contains cyanogenic glycosides. All agree, however, that the greatest current use for sycamore is as an ornamental tree, particularly in parks and along streets.

### *Pleopeltis*

(From Greek *pleos*, full or many, and *pelte*, a shield, in reference to the paraphyses)

*Pleopeltis polypodioides*. From Britton and Brown 1896.

***Pleopeltis polypodioides*** (resembling *Polypodium*) (= *Polypodium polypodioides*)

*coladilla* (little tailed one)

*doradilla* (little golden one, Cuba, Dominican Republic)

*fougere grimpante* (climbing fern, French Antilles)

gray polypody (a book name, Bahamas)

*helecho que resucita* (resurrection fern, Dominican Republic); resurrection fern (USA)

*ihosi:cokhissi* (*ehose*, a mystical being who causes people to get lost, *kokhesse*, whiskers, Creek); *iwa:satkáhcicô:skî* (cognate to the Creek name, with the same meaning, Mikasuki)

*istilibuski entaapente* [*yaato posheke entaapente, yatapushkaale entaapente*] (*isti*, person, *libuski*, little, *entaapente*, his fern, Mikasuki)

*koo' te'* (tree caretaker, Huastec, San Luis Potosí)

*kutsiil Boo'waat* (*Boo'waat* dance baton, Huastec, San Luis Potosí)

*lakcv-cvmpv sohhontat* (little thing that sprouts on sweet acorn [live oak]; *lakcv*, acorn, *cvmpv*, sweet, *sohhontat*, from *s-*, with, *oh-*, on, *hont-* sprout, *us-*, little, *-at*, the one that, Creek)

*liane anolis* (lizard [*Anolis*] fern, Haiti)

*liane couresse* (running fern, French Antilles)

*okecheske entapente* [*okiciskintapinti*] (*okecheske*, many small bases, *entaapente*, its fern, Mikasuki)

*polypode* (many foot, French Antilles)

*tsooy ahaatik* (lord rib, Huastec, San Luis Potosí)

weering grass (Creole, Nicaragua)

*Pleopeltis* is often included within *Polypodium*. As now circumscribed, it contains 11 to 50 species (Andrews and Windham 1993, Mabberley 1997).

Resurrection fern is one of the most widespread ferns in the New World, ranging through much of the eastern United States south through most of Latin America (Andrews and Windham 1993). The Houma made a cold infusion of fronds used to treat babies' sore mouths (thrush) and use a decoction of the fronds for headache, bleeding gums, and dizziness (Speck 1941). The Seminoles used the fern in a complex mixture to treat chronic sickness, certain kinds of mental problems, and in certain medicines used in childbirth (Sturtevant 1955). Bennett (1997) found that modern Seminoles mix *P. polypodioides* with shoestring fern (*Vittaria lineata*), boil it in water, and drink the decoction, or administer it in a steam bath to treat depression. They also told him that the plant was used in another medicine but would not share particulars with him. Alice Snow calls the plant *okecheske entapente* (Snow and Stans 2001).

In Cuba, *doradilla* is considered a prime remedy for liver problems (Roig 1945). Some there also think it good for heart problems. Whole plants, but mostly the leaves, are put in water containers and give a slight earthy flavor. In Roig's time, there was a patented remedy called *Elixir de Doradilla*.

The plants are considered a cure for liver problems in Hispaniola (Liogier 1974). Morton (1981) found the dry fern being sold by herb vendors in Puerto Rico as a remedy for high blood pressure, and Hocking (1997) found that the entire plant had been used for

bronchitis. In Mexico, Alcorn (1984) found the Huastec used the fern to treat fever and dizziness, and to scrub the head. A tea is made from the fern to clean the stomach and lungs in Nicaragua (Barrett 1994).

### ***Pluchea*: Cure-for-AH**

(Named to commemorate the French abbot NoëlAntoine Pluche, 1688–1761, a seminary teacher and naturalist)

In 1817, the French botanist Alexandre Henri Gabriel de Cassini (1781–1832), who specialized in the Asteraceae, described plants in a new genus he called *Pluchea*. The reference species (type) of the genus is *Pluchea marilandica*, which another French botanist, André Michaux, previously had placed in the genus *Conyza*. Indeed, Michaux was following Linnaeus who placed in *Conyza* several species that today are segregated into other lineages.

Such changing of names is a normal part of scientific learning because evolution has selected among different phylogenies to the point that they are difficult to distinguish. Not only have scientists had trouble sorting out the genera and species in the Asteraceae, but nonscientists sometimes apply names in what appear to be random ways. However, there are two frequent and essentially tropical *Pluchea* that people use across their ranges. Of the five native species in Florida, this discussion focuses on *P. carolinensis* and *P. odorata*. The second of these also appears in the literature under the names *P. purpurascens* and *P. symphytifolia* (Gillis 1977, Khan and Jarvis 1989), so it is often difficult to sort out uses. Since both species have mostly the same applications, exact identity is not critical.

Only two indigenous common names were found in the southeast. The Choctaw call *P. foetida hoshukkosona* (*haskuk*, grass, *kosoma*, strong smell), and they boiled the leaves and used the water extract “during attacks of fever” (Bushnell 1909). The Koasati call *P. camphorata ittohapakó* (*ittó*, tree, *hapakó*, death), and also used it to treat fever (Taylor 1940). Given the importance of the plants to the remaining Americans, other linguistic groups probably also had names for them.

In Mexico, the Aztecs knew these plants and used them. Both *P. carolinensis* and *P. odorata* were known as *ciguapatle* [*ciguabate*, *cichapatle*, *cipatle*, *seguapeti*, *siguapete*, *siguapote*], a name derived from *cigua*, woman, *patl*, medicine (Nahuatl, Mexico to El Salvador). However, alternate names were applied.

*Pluchea. Pluchea foetida* . From Britton and Brown 1898. *Pluchea odorata* (right), a. Tip of flowering branch, b. Enlargement of leaf showing glandular pubescence, c. Flower head, side view. d. Perfect disk flower, side view. e. Perfect disk flower, longitudinally dissected, f. Floral diagram of perfect disk flower, g. Pistillate disk flower, side view. h. Pistillate disk flower, longitudinally dissected, i. Floral diagram of pistillate disk flower, j. Achene with pappus. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Perhaps *comalpatli* (*comal*, cooking disk to prepare tortillas, *patl*, medicine) is simply another way of saying woman's medicine, because cooking is traditionally considered the female realm. Probably both *ahuapatli* [*alaa-patl*] and *nahuapate* [*nahuapote*] are variants of *nahuac*, of *anahuac* (Mexico, El Salvador), meaning a medicine growing near water. Both species are most frequent near marshes. Perhaps the modern *hoja de la playa* (beach leaf) comes from the Nahuatl source.

To the Mayas, both plants were *chal-ché* [*chalchay*, *chalche*, *chalché*, *ix chal-ché*, *chal-ch*, *caal-ca*] (wash quickly, Maya, Yucatan, Belize, Guatemala, Nicaragua). That name is an allusion to medical use before, during, and after childbirth, much as in the Nahuatl names.

Several apparently indigenous names applied in different areas have not been translated. These include *alinanche* (Sinaloa), *clina*, *suquinay* [*suquinayo*] (Guatemala, El Salvador), *teposa*, and *tewa Zahn* (Zapotec, Oaxaca).

Perhaps the most widespread view of these plants is shown by the names cure-for-all [curforal] (Florida, Barbados), and *guérit-tout* [*gueritoute*, *gueri-tout*, *guérir ton*, *jewi tut*] (cure-all, Haiti, Guadeloupe, Martinique). Most of the common names clearly indicate medical applications. Both cough bush (Bahamas) and sour bush (Bahamas) note usage as a remedy for colds and associated symptoms (Morton 1981). Although the simple comment that the leaves are smoked like tobacco is in the literature, the many names comparing the leaves with *Nicotiana* surely suggest an adjunct to relieve cold symptoms. Among those names are bitter tobacco (Jamaica), Indian tobacco, riverside tobacco, *tabac à Jacot* [*tabac à jako*] (false tobacco, Haiti), *tabac diable* (devil's tobacco, Haiti, Guadeloupe, Martinique), *tabac marron* [*tabac mawon*, *tabac sauvage*] (wild tobacco, Haiti), *tobacco cimarron* (wild tobacco, Panama), *tabac zombie* (ghost tobacco, French Antilles), and wild tobacco (Bahamas, Jamaica).

Of these names, *tabac à Jacot* requires some explanation. The name *Jacot* [*Jacquot*] is used in a game English speakers call "Simon Says." In the game "*Jacques* [or *Jacquot*, the diminutive] *a dit*" one imitates as a parrot [*Jacquot*] imitates people. So, the plants "imitate" the real tobacco.

Some of the names that allude to medicinal uses are obtuse as in *feuilles la chose* (the thing's leaf, Haiti), fox-leaf, *la chause* [*la chose*, *la choille*, *la choise*, *la choige*, *la choy*] (the thing, Haiti), both applied to *R. carolinensis*.

Several of the names with religious references are notations of medical applications. These include *flor de angel* (angel flower) and *flor de Guadalupe* (Gua dalupe's flower), applied to only *P. odorata*, and *hierba de Santa María* (Saint Mary's herb, Mexico, Nuevo León), given to *P. carolinensis* and *P. odorata*. Others say *Santa María* (Saint Mary, Tamaulipas, Veracruz, Yucatan, Belize, Nicaragua) or *Santa María cimarron* (wild Saint Mary).

Several people compare these aromatic shrubs with *salvia* (Latin, to save or preserve) not only because both are aromatic, but also because both are medicines that "preserve" health. In French, both *P. carolinensis* and *R. odorata* are *grande sauge* (Haiti, Martinique, Guadeloupe), [*la*] *sauge* (sage, Haiti), or *sauge rouge* (red sage, Haiti, Martinique). In Spanish, they become *salvia* (sage, Puerto Rico, Dominican Republic, Nicaragua), *salvia colorada* (red sage), *salvia de remedios* (medicinal sage, Dominican Republic), *salvia blanca* (white sage, Dominican Republic), *salvia cimarrona* (wild sage, Cuba), *salvia de playa* (beach sage, Cuba), *salvia del país* (country sage, Cuba), *salvia real* (royal sage), or *salvia santa* (holy sage). Although it is not at first obvious, the name *saab* [*saav*, *big-saab*] (Bahamas) is probably a Creole version of *salvia*. Other names that note the fragrance are camphor-weed (*P. odorata*, Florida), *canela* [*canelón*] (cinnamon, Mexico, Baja California), or sweet scent (Puerto Rico, Virgin Islands).

Until the early 1800s, many species now considered *Pluchea* were placed in the genus *Conyza* (Greek, a flea), and the Greek gave rise to the common name *conyze odor ante*

(fragrant horsetail, Dominican Republic). *Conyza* was originally used by Dioscorides (fl. A.D. 40–80) for some kind of fleabane, so the Hispaniolan name follows a venerable usage although the original was a Mediterranean plant. Several members of the Asteraceae have been considered “fleabanes” and used to repel those annoying animals (see *Erigeron*). *Pluchea carolinensis* too is called bushy fleabane (Bahamas), hairy fleabane, and shrubby fleabane (Bahamas). Both *P. carolinensis* and *P. odorata* are called sweet-scented fleabane (Bahamas, Jamaica, Trinidad), but usually only the latter is [salt] marsh fleabane (Arizona to Florida). Their names suggest they have been used to repel fleas.

Some of the names denote other uses or comparisons. In Guadeloupe and Martinique, *P. odorata* is *bois liege* (cork bush), and the wood is presumably the part used. People in Belize say *pito sico*. A *pito* is a flower, and *sico* may be a variant of *seco*, dry, probably a name used like “straw-flower” in English, because of the dry flowers. Perhaps *corail* (coral, Haiti) notes the pinkish flowers. Any resemblance to a *z'orielle mouton* (sheep's ear, French Antilles) must also have to do with pubescence, as both are white and woolly. Residents of Mexico call *P. odorata* the *jara*. It is not clear if they are comparing the species with rockrose (*Helianthemum*, Sonora) because both have white pubescent leaves, or if they are calling it an “arrow” (the Spanish from Hebrew *khara*, to cast).

The common name cure-for-all is an exaggeration, but both species are used to treat many problems. Among the afflictions treated are asthma, bronchitis, cholera, colds, digestive and eye complaints, fever, gout, headache, hoarseness, hypertension, menstrual difficulties, nervousness, neuralgia, night sweats, rheumatism, sores, spasms, stomach disorders, swelling in any part of the body, toothache, twitching muscles, and wheezing. They are also used to treat new mothers and women in labor (Standley 1920–1926, Roig 1945, Martinez 1969, Morton 1981).

Laboratory studies have shown that *P. odorata* has antifungal, antimicrobial, antibacterial, and anthelmintic properties (Dominguez and Zamudio 1972, Lopez-Abraham et al. 1979, Scholz et al. 1990, 1994). These traits apparently stem from terpenes. Most of the known compounds in *P. odorata* are sesquiterpenes (Dominguez et al. 1981, Arriaga-Giner et al. 1983, Arriaga and Borges-del-Castillo 1985, Ahmad et al. 1992a,b, Loayza et al. 1992, Ahmed et al. 1998). Sesquiterpenes also are among the most reported chemicals in other species (Ahmad and Fizza 1988a, b, Ahmad et al. 1989a, 1991, 1992a,b, Ando et al. 1994, Zdero and Bohlmann 1989, Uchiyama et al. 1991, Guilhon and Muller 1996, 1998, Mahmoud 1997, Shimoma et al. 1998). However, monoterpenes, triterpenes, and triterpenoids are known to have similar properties (Uchiyama et al. 1991, Kaith 1996, Perez-Garcia et al. 1996). Also reported are antiinflammatory (Srivastava et al. 1990, Sen and Nag Chaudhuri 1990, 1991, Sen et al. 1993a, Perez et al. 1995), anti-ulcer (Pal and Chaudhuri 1989, Sen et al. 1993a), hepatoprotective (Sen et al. 1993b), and trypanocidal (Zani et al. 1994) properties.

Common names indicate an ancient Náhuatl and Mayan application for women, especially during and after childbirth, and suggest an original specialized medicine. With the influx of several European cultures and confusion with the Old World fleabanes, that specialization may have given way to a broader utilization. Indeed, considering the array of uses for *Pluchea*, it is easy to see why it became known as a cure-for-all or *guérit-tout*. Given the Old World use to treat poisonous snakebites, it is surprising that people in the

New World did not include that among their pharmacopoeia. Experimental data for *Pluchea* actually indicate that it works for that problem (Alam et al. 1996).

### ***Plumbago*: Plumbago or Leadwort**

(Latin *plumbum*, lead, *ago* from *agere*, to bear or resemble)

***Plumbago scandens*.** a. Flowering branch, b. Detail of node. c. Flowering and subtending bract and bracteole. d. Stamens, front and side view. e. Gynoecium, with details of stigma and ovary. *Drawn by Bobbi Angell From Acevedo 2003.*

The word “plumbago” appeared in English by 1784 although it has a venerable history in southern European languages. Most speakers of English call the plants leadwort. Both names refer to the genus *Plumbago* and the family Plumbaginaceae. The history of the words “plumbago” and “leadwort” is long and complicated, and sometimes the plant is inseparable from the metal except by inference.

Dioscorides (fl. A.D. 40–80) used two Greek words to designate both a metal and a plant. Pliny (A.D. 23–79) Latinized those words as *molybdaena* and *plumbago*, and used both for what is now *galena*, lead ore. However, for the plants, Pliny always used *plumbago*. In Philemon Holland’s 1601 translation Pliny says, “There groweth commonly an herbe named in Greeke Molybdaena, that is to say in Latin, Plumbago, euen vpon

euery corne land.” Matthioli’s *Commentary on Dioscorides* was translated into French in 1572, and subsequently most French, Italian, and German speakers reapplied “plumbago” to the metal. Linnaeus (1753) formalized the use of *Plumbago* to the plant and it has remained that way.

The white plumbago (Bahamas, Puerto Rico) in southern Florida is *P. scandens*. That sprawling herb is also found in the Bahamas, the West Indies, Mexico (Sonora and Tamaulipas south) to Costa Rica and South America to Peru, Bolivia, and Argentina. The plant has multiple names throughout its range because it is notorious for several reasons.

The names for the American plants were complicated because Europeans already knew *P. europaea*. They called the Old World plants by two sets of names—one mentioning the metal lead, and the other teeth.

Mostly, *P. europaea* is associated with the metal in the names leadwort (English), *piombaggine* (lead plant, Italian), *plumbago* (Sonora, Spanish), and *Bleiwurz* (lead herb, German). Those names are either based on an old belief that it could be used to cure lead poisoning (Bremness 1994), because of the “leadcolored” flowers (OED 1971), or because the roots impart a lead color to the hands when handled (Walker 1976). Few English speakers recognize the word plumbago, and they use its translated form, leadwort. According to Nathan Bailey’s *A Universal Etymological English Dictionary*, “leadwort” was first used in English in 1727.

The other names for *P. europaea* are based on its use in treating toothache. Surely the oldest name of those referring to teeth was *Lepidium Dentillaria dictum* (little scale called dentillaria) published by Gaspard Bauhin in 1623. That name evolved into *dentelaire* (French) and *dentildria* (Portuguese). This knowledge of use was carried to the Americas where *P. scandens* became *dentelaire* [*dentelie*] (Haiti) and *dentelária* (Oaxaca, Cuba).

The European Spanish *hierba blesa* (pretty herb) and *velesa* (pretty one) are related, and these were applied to *P. scandens* as *belesa* [*beleza*] (Puerto Rico). These probably gave rise to *bella Emilia* (pretty Emily, Dominican Republic, Colombia, Argentina), *belleza enredadera* [*veleza enredadera*] (pretty twiner, Puerto Rico), and *embeles* [*embeleso*] (Yucatán, Cuba). There is either a linguistic relationship between these and Spanish *embelesar* (to enchant) because of the beauty of the flower or simply as a result of confusion with that word.

Throughout the Americas, there is an ambiguity of feelings toward these plants that is typified by *homme à] deux faces* (man with two faces, Haiti). The herbs are pretty because of their flowers, but like their European cousin, they are “acrid, blistering, and emetic” (Polunin 1969). Many of the common names warn against those traits.

Some of the names are direct, as in blister leaf (Virgin Islands), *chilillo* (little pepper, Veracruz), *herbe brûlante* (burning herb, Guadeloupe, Martinique), *queimadeira* (burner, Brazil), *same vejiguilla* (blister herb, Peru), *yerba de vejigatorio* (irritant herb, Guyana), *tlalchinchinolli* (from *tlachichinacapolli*, cruelly tortured, Náhuatl, Quéretaro), and *tlepatli* (fire medicine, Nahuatl, Quéretaro). Others damn them by inference or association, as in *caataia* (*caa*, plant, *taia*, from *ta’yá*=*Zanthoxylum violaceum* in the Rutaceae, a family famous for volatile oils, Tupi, Brazil), *folhas de louco* [*louco*] (crazy leaf, Brazil), *malacara* (bad-face, Cuba), and *herbe bourrique* (sheass herb, Haiti). Surely, the fiery juice led to the comparison with mustards and the names *moutard pays*

(wild mustard, Guadeloupe, Martinique) and *sinapisme* (from Latin *sinapis*, mustard, Guadeloupe, Martinique).

Some people consider the plants the devil incarnate, with *erva do diabo* [*erva de diabo*] (devil's herb, Brazil), *herbe au diable* (devil's herb, Haiti), *hierba del diablo* [*yerba del diablo*] (devil's herb, Dominican Republic, Colombia, Argentina), and *mauvaise herbe* (damned herb, Haiti). At the opposite extreme, some people consider them an *erva divina* (divine herb, Brazil).

Other names are more obtuse allusions to medicines. These include doctor-bush [doctorbush] (Bahamas, Florida), *herbe à Madame Bihoret* [*zèbe Man Bihoret*] (Guadeloupe, Martinique), *folha de louro* (parrot leaf, Brazil), *hierba del negro* (negro's herb, Oaxaca), *hierba del pajar* (bird's herb, Panama), *hierba de alacrán* (scorpion herb, Sinaloa, Jalisco, San Luis Potosi, Oaxaca, Guanajuato), *lagaña de aura* (vulture's eyelid, Cuba), *lagaña de perro* (dog's eyelid, Morelos, Cuba), and *muela de alacrán* (scorpion's molar, Mexico).

People also find the sticky fruits worthy of comment. Some of these names are positive, such as *collant* (sticky one, Guadeloupe, Martinique), *erva de amor* (love herb, Brazil), and *meladillo* [*melallillo*, *mielilla*] [*silvestre*] ([wild] honey-giver, Puerto Rico, Cuba, Mexico). Typically, *meladillo* is applied to *P. auriculata* in Puerto Rico. Other names are negative, as in *pegajoso* (sticky one, Tamaulipas, Sinaloa), *pegapollo* (chicken-catcher, Dominican Republic), *pegoso* (sticky), *mata-pollo* (chicken-killer, Dominican Republic), and *visqueira* (the viscous one, Brazil).

Some people do not know of the medicinal uses. They may be the ones calling the plants *canutillo* (little tube, maybe the flower, Sinaloa), *guapote* [*guapito*] (from *guapo*, handsome, Venezuela, Peru), *estrenina* (little gift, Sonora), *Isabel* (Hispaniola), *jazmin azul* (blue jessamine, Yucatan), and *jazmin azul* (blue jessamine, Brazil).

Several indigenous names are descriptive or simple terms. Among those are *caajandiva* [*caajandivas*] (*caa*, plant, *jandiva*, from *nandia*, catfish, Tupi, Brazil), *caaponga* [*caapononga*, *caponga*] (*caa*, plant, *ponga*, climber, Tupi, Brazil), *chabak* [*chab-ak*, *chabac*, *chapak*] (*chab*, bad odor, *ak*, vine, Maya, Yucatan), *guacochile* (if Nahuatl, maybe from *uactoc*, mature, *chilli*, chile, El Salvador), *guaicuru* (maybe Taino), and *turicua* [*tiricua*, *jiricua*] (Guanajuato, Tamaulipas). The Huastec call it *hurika*, and some people have spelled that *eureka* (San Luis Potosi). The second spelling has no linguistic relation to "eureka" in English.

Leaves and roots when applied to the skin produce almost instant reddening and in a short time blisters. An external decoction is used to treat erysipelas, felon, itch, mange, warts, external ulcers, leprosy, and similar problems (Bye 1986). Root juices have also been used to cauterize ulcers in horses (Mors et al. 2001). The same parts are poisonous if taken internally (Tokarnia and Dobereiner 1982, Medeiros et al. 2001, Mors et al. 2001). *Plumbago europea* has similar properties and is used as an emetic; when chewed, the plant increases saliva flow. Roots are used from both species to relieve pains in ears and teeth, for swollen joints, and as a purgative (Mors et al. 2001). Beggars have applied the leaves to raise sores on their body to arouse pity (Standley 1920–1926). Leaves and roots are macerated in alcohol and applied to the skin to treat rheumatism (Pittier 1926, Petersen 1974, Liogier 1974).

Roots and leaves contain plumbagin (Harborne 1967), a naphthoquinone derivative characteristic of most species in the genus (Mors et al. 2001). There are related

compounds in *P. scandens* and other species (Sankaram et al. 1979, Bhattacharyya and Carvalho 1986, Dinda and Chel 1992, Dinda 1994, Gupta et al. 1999). Plumbagin is active against several fungi and bacteria (Gongalves de Lima et al. 1968, Vijver and Lotter 1971, Bambode and Shukla 1974, Durga et al. 1990, Ahmad et al. 1998, Ali-Shtayeh and Abu Ghdeib 1999, Beg and Ahmad 2000). In addition, plumbagin and related compounds have shown promise in cancer treatment, for inhibiting inflammation, in controlling cholesterol, and improving cardiotoxic action (Melo et al. 1974, Itoigawa et al. 1991, Sharma et al. 1991, Oyedapo 1996, Devi et al. 1999).

Several studies show that the chemicals in *Plumbago* inhibit feeding by insects (Kubo et al. 1980, Sharma 1984, Hassanali and Lwande 1989). In spite of the potpourri of toxins in the plants, one genus of North American butterfly uses *Plumbago* for its larvae. Those animals are butterflies in the genus *Leptotes*, but specifically *L. cassius* (Cassius blue) and *L. marina* (marine blue) use *Plumbago* (Brown 1990, Minno and Minno 1999). How the larvae of those tiny blue gems can ingest the scalding compounds with immunity is unknown. Yet, when they become adults, they can also sip nectar from the flowers.

### *Podophyllum*

(From Greek *pous*, *podos*, a foot, and *phyllon*, a leaf; Linnaeus modified the name from Catesby's *Anapodophyllum*, duck foot leaf)

***Podophyllum peltatum*.** From Britton and Brown 1897.

***Podophyllum peltatum*** (shield-shaped)

behen (from Medieval Latin *behen*, corrupted from Arabic *bahman* [*behen*], a kind of root; the word appeared in English in Henry Lyte's 1578 translation of Dodoens's *Cruydeboek* of 1554 as "Called...of herboristes at this day Behen, or Been album")

*che-sa-ne-pe-sha* (it pains the bowels, Osage; also called *shon'-gthin-dse*)

*citron* (fruits resembling *Citrus medica*, among the French in 1700, Missouri); *citron sauvage* (wild citron, *Citrus medica*, Quebec)

devil's-apple; hog apple (Iowa); Indian apple; mugapple

duck's foot (in use by the 1730s by Catesby); wild duckfoot

*fala imisito* (*fala*, crow, *im*, its, *isito*, pumpkin, Choctaw); *fala intanchi* (*fala*, crow, *in*, its, *tanchi*, corn, Choctaw); *falaanosi* (*fala*, crow, *aanosi*, bed, Chickasaw)

ipecacuana (from *ipega'kwai*, duck's penis, or *ipekaa-guéne*, creeping plant causing vomiting, Tupi, Carolinas, Catesby 1731–1732)

*kypotoyv* [*'kypotoyv*, *kypoloye*] (*kypoteyetv*, something to put on the head, Creek)

[ground, wild] lemon; yellow-berry

*Maiapfel* (May apple, German); May-apple [American, common, mayapple] (Catesby called the herbs May Apple in 1731, although the OED 1971 says the name dates from Philip Miller in 1733 as *Pomum Maiale*, May apple; either way Catesby found it in local use in the Carolinas by the 1720s); *pomme de mat* (May apple, Quebec)

[American, wild] mandrake[-pear] (pear-like fruits, compared with *Mandragora officinarum*, New Jersey)

*mäskätámin utcípa* (*mäskätä*, defecation, *mín*, berry, *utcípa*, root, Menomini); *maskiichtew* [*masgichteu*] (*maashk*, defecating, *kiich*, causes, Delaware)

maypop (a name usually applied to *Passiflora*, Virginia)

parasols (an allusion to the leaves, Ohio); umbrella plant [root] (Virginia)

*podophylle* (French)

Puck's foot ("Puck," from Old English *puca*, Old Norse, *púki*, Welsh, *pwca*, Irish *púca*, a mischievous demon; it is not clear if the word is of Teutonic or Celtic origin, but it was in English by about A.D. 1000; Middle English *the pouke* was identified with the devil; from the 16th century, as Puck, a tricky goblin or sprite; also called Robin Goodfellow, Hobgoblin; all three were used by Shakespeare in 1590)

raccoon berry (from *ärä'kun*, for *Procyon lotor*, Virginia Algonquian; in use by 1884)

vegetable-calomel ("calomel," from Greek *calos*, beautiful, *melos*, black or from Ethiopian *calos*, beautiful, *melos*, black, because white or pale bodies rubbed with it become black; mercurous chloride [ $\text{Hg}_2\text{Cl}_2$ ] or *mercurius dubius*; used as a laxative in medicine from 1676)

vegetable-mercury (the same allusion as "calomel")

wild jalap ("jalap," from *xalli*, sand, *ail*, water, *pan*, upon, Nahuatl, used to identify the city as Xalapa and, in this context, *Ipomoea purga*, by 1675)

When I was still a child, I was told that there were “male” and “female” plants of May apples. They were easy to tell apart, because the “male” had a single leafstalk, and the “female” had a branched leafstalk with a leaf on each branch. Moreover, the “female” had flowers in the place where the stalks split into two. I was skeptical. I planted some near my home. Each rhizome node (joint) bore a single leaf—which was unbranched one year and branched the next. So much for male and female plants.

The first record Linnaeus had of these plants was in German physician Christian Mentzel’s (1622–1701) book of 1682, the *Pinax*, where he called them *Aconitifolia humilis, flore albo unico campanulato, fructu cynosbati* (A weak herb with leaves like Monk’s-hood, a single, bell-shaped, white flower, a fruit like a dog briar). Mark Catesby (1731–1732) called the plants *Anapodophyllum canadense* (duck foot leaf from Canada). Thankfully, Linnaeus shortened the name to *Podophyllum* in his *Hortus Cliffortianus* of 1738. Catesby added that, because the herb flowers in May, the local residents in South Carolina called it “May apple.”

*Podophyllum* has two species (Mabberley 1997). *Podophyllum peltatum* is endemic to the eastern United States and ranges from Florida to Quebec and Ontario in Canada, and west to Minnesota and eastern Texas (Fernald 1950, Correll and Johnston 1970, Diggs et al. 1999). The other species, *P. hexandrum*, grows from the Himalayas to eastern Asia, including Afghanistan, Pakistan, northern India, and China (Hsu 1986, Hocking 1997).

Fernald et al. (1958) noted that the fruits are relished by most individuals when fresh, although Harvard guru Asa Gray (1810–1888) was the exception. Gray wrote that the fruit was “mawkish, eaten by pigs and boys.” Although the taste is “peculiar,” as Fernald et al. (1958) described it, the flavor is agreeable. Native people in the Americas concurred. At least the Cherokee, Delaware, Iroquois, Menomini, Meskwaki, Osage, Penobscot, and Ojibwa ate the fruits fresh, cooked, or mashed and made into small cakes that were dried for future use (Hunter [1823] 1973, Yanovsky 1936, Vogel 1970, King 1984, Moerman 1998). As needed, the cakes were soaked in warm water, cooked as a sauce, or mixed with corn bread.

There are accounts of indigenous people committing suicide by eating the root of May-apple (Vogel 1970). Because the roots are purgative, emetic, and irritating, that would be an excruciating way to die, although Benjamin S. Barton wrote in 1810 that the root was “possessed of some degree of an anodyne, or narcotic quality.”

The Cherokee used *Podophyllum* to treat intestinal worms, rheumatism, ulcers, and sores, as a laxative, and dropped in the ears “to restore hearing” (Hamel and Chiltoskey 1975). The Choctaw treated biliousness with the root (Swanton 1931). The Delaware used the herb as a laxative and spring tonic (Moerman 1998). The Iroquois used it as a strong physic, to treat boils, as a laxative, and as a poison to soak corn seeds in before planting. The Menomini also used it to kill insects on cultivated plants (Mahr 1955a). The Meskwaki used the root to treat rheumatism, as an emetic, and as a physic (King 1984). The Osage used the powdered root as a cathartic, gave it as an antidote for poison, and used it to ward off fever (Hunter [1823] 1973). The Penobscot used May-apple to cure warts (Vogel 1970).

Tiny quantities of roots, leaves, or green fruits are poisonous, and powdered root and resin can cause skin and eye problems. *Podophyllum peltatum* contains more than 15 biologically active compounds, including podophyllin, and a bitter resin containing lignins and flavonols (Diggs et al. 1999). Podophyllin, concentrated in the root, is the

drug of choice for treating genital warts although it is highly allergenic (Foster and Duke 1990). Etoposide, a semisynthetic derivative from the roots, is the first-choice drug for treating small-cell lung carcinoma and testicular cancer (Foster and Duke 1990, Coffey 1993, Hocking 1997, Mabberley 1997, Swerdlow 2000). Teniposide is used to treat brain tumors and childhood leukemia (Swerdlow 2000). *Podophyllum hexandrum* has larger rhizomes than the American species and contains more resins (12%) with about twice the content of podophyllotoxin than *P. peltatum* (Hocking 1997). *Podophyllum hexandrum* also contains podophyllotoxin, desoxypodophyllotoxin, isopicropodophyllone, astragalin, hyperin, quercetin, and kaempferol (Hsu 1986).

The major disperser of *P. peltatum* in Delaware forests is the box turtle (Mabberley 1997). Apparently, that is why the herbs can get away with “hiding” their fruits below the canopy of leaves where birds and many other animals have difficulty finding them.

### *Polygala*: Milkworts

(From Greek *poly*, much, *gala*, milk)

Milkworts are everywhere in the pine flatwoods in late April. Sometimes thousands of plants belonging to nine species will be in view on ridges and swales. As I look at the plants, I can almost see the Greek physician and author Pedanios Dioscorides from the

*Polygala*. a. *Polygala cruciata*. b. *Polygala lutea*. c. *Polygala*

*grandiflora*. d. *Polygala rugelii*. e through k. *Polygala nana*. e. Habit, f and h. Keel, two views, g. Flower, i. Filaments connected to petals, j. Mature seed. k. Pistil, *a through d drawn by P.N.Honychurch. e through k drawn by Vivian Frazier*. From Correll and Correll 1972.

1st century A.D. selecting samples. Bending over, he gently snaps off the stems, and thinks that the bitter plants will produce *polygalon* (much milk). They will be useful to the farmer who had recently come to him for help renewing the flow of milk in his cow. Dioscorides tucks the plants gingerly into a small bag he has draped over his shoulder and walks on.

Speakers of different Mediterranean languages called these plants their linguistic equivalents of milkwort (wort, plant) long before the Dutch herbalist Rembert Dodoens published the Latin name in 1554. Henry Lyte's translation of Dodoens's Dutch text on *Polygala* says that it "engendreth plentie of milk; therefore it is good to be used of nurses that lack milk." Others following this idea include Italian *poligala*, Spanish *hierba lechera* (milk giving herb), Portuguese *erva leiteira*, and French *latter* (milk giver). Gaels also call them *lus a'bhainne* (milk herbs). In spite of these names and beliefs, there is no experimental evidence that the plant extracts increase milk flow.

Europeans know the plants by other names. Norwegians call them *blåfjaer* (blue-flower). While not all their species have blue flowers, they retain the basic name and add modifiers, such as *bitterblåfjaer* (*P. amarella*) or *storrblåfjaer* (*storr*, big, *P. vulgaris*). In Guernsey *Polygala* is *herbe de paralysie*, and it is used to treat or prevent paralysis or strokes. Gaelic speakers in Scotland call the herb *saibann nam bansidh* (fairy women's soap). Indeed, many species contain saponins (soaplike compounds). The Germans call it *Kreuzblume* (cross-flower). One can see a resemblance (with considerable imagination) to a cross in the flowers.

Many of the Florida species have common names that reflect their colorful flowers. Bachelor's buttons, the least creative among these, was adopted from unrelated European plants (*Centaurea cyanus*, Asteraceae). Sometimes that name is applied to all the species, but there are more often modifiers, as in white bachelor's-button (*P. baldunii*) bog bachelor's-button (*P. lutea*), dwarf bachelor's-button (*P. nana*) and yellow bachelor's-button (*P. rugelii*).

Some of the more intriguing common names for milkworts are given to *P. cruciata* (drum-heads) and *P. pauciflora* (gay-wings, bird on the wing, baby's toes, baby's feet, baby's slippers, satin flower, Indian pink, maywing). However, the most curious names for Florida's *P. incarnata* are procession-flower or Rogation-flower, both of which it shares with European *R. vulgaris*. Herbalist John Gerarde in 1597 explained these names by saying that the plants "flourish in the Crosse or Gang weeke, or Rogation weeke; of which floures the maidens which use in the countries to walk the Procession doe make themselves garlands and noseгаies, in English we may call it Crosse-floure, Rogation floure, and Milkewort, of their virtues in procuring milk in the breasts of nurses."

Rogation Sunday is the fifth Sunday after Easter, and it is followed by Rogation Week when church processions (or “gangs”), led by a person carrying a cross, bless crops. This may be another pagan ritual incorporated into the Christian religion, because there is a word in Gaelic for the procession—*liodan*.

Milkworts, also known as candyweeds or candyroots (because of a licorice taste to the roots of some), are small herbs in North America and northern Europe, but in drier climates and within the tropics they may be shrubs or even trees (Mabberley 1997). Some species produce dyes, and one from tropical Africa (*R. butyracea*) yields a fiber.

Many species around the world are used in medicines, although only one in North America has received much publicity. That northern species, *R. seneca* (snake-root, Seneca snakeroot), became famous as a snakebite remedy when the first Europeans arrived in the New World. Although its effectiveness in treating snakebite is doubtful, the species became popular for treating pleurisy, the most common ailment in colonial Virginia (Coffey 1993). Even William Byrd (1674–1744), one of the surveyors of the line between North Carolina and Virginia, used it to treat gout in a member of his party in early 1728 (Byrd [1728] 1980).

Snake-root contains the glucoside senegin (a saponin), polygalic acid, resin, methyl salicylate, and fatty oils (Hocking 1997). Several of these make the plant potentially effective in medicines as an emetic, expectorant, cathartic, diuretic, antispasmodic, and sweat inducer, to regulate menses, for colds, and against croup, pleurisy, rheumatism, heart troubles, convulsions, and coughs, and as a poultice against swelling. The presence of methyl salicylate also supports its use against some of these maladies. This chemical is more familiar under the name of “wintergreen” and it has long been used in medicine and flavorings. Florida’s *R. boykinii* shares methyl salicylate with others, and has been used in Mexico in a cold water infusion to correct dizziness (Hocking 1997). Similarly, Seminoles told Sheehan in 1919 that it was a medicine for treating vertigo (von Reis and Lipp 1982).

Pollen of the genus has been found in the preColumbian deposits at the Glades site of Fort Center on the western side of Lake Okeechobee (Hogan 1978). The Seminoles have different names for *P. rugelii* and related species, but they seem to use each one as a generic term for several species. The species has had religious significance in Florida for a long time, and this relationship is indicated by the Micco sukee name *sápiyá:bí* or *sápiyi* (resembling the mythical plant “*sápiyi*”) (Sturtevant 1955). Snow and Stans (2001) used *sypeyv* as the Creek name.

A more detailed explanation of *sypeyv* is given by Martin and Mauldin (2000). They wrote that this is the name of “a plant whose root is used as a charm,” basing their comment on some notes made by Mary R. Haasca. 1940. For the second meaning, they added, “a charm (once used for hunting, but now used to attract a suitor).”

Sturtevant (1955) wrote that the Creeks called *Poly gala*, regardless of the species, *hl’lamási* (*hele*, medicine, *em*, its, *vse*, tea, Creek). He was told that they used both *P. lutea* and *P. rugelii*, but that the former was better. His informants used *Polygala* for “Sapiyi Sickness” (heart palpitations, yellow skin, body swelling, shortness of breath), “Chronic Sickness,” snakebite, birth medicine, and sorcery.

Snow and Stans (2001) added the Creek names *sypeyv hvlwat* (*sypeyv*, polygala, *hvlwv*, high, *-at*, the one that is), and *sypeyv lopockuce* (*sypeyv*, polygala, *lopocke*, small, *uce*, small), plus the Mikasuki names *wootaacheeke em oekekche* (properly *wootaacheeke*

*em alekche*, emetic medicine; from *wootaach-*, make vomit, *-eeke*, thing that, i.e., emetic, *em*, its, *alekche*, medicine), *tofoome chayhe* (*chayhe*, tall, Mikasuki; the first word may be cognate with Creek *eto-home*, bitter wood), and *shapeye peshkooshka* (small polygala). Bennett (1997) was told the Mikasuki name *eeye mashe* (*eeye*, foot, *em*, its, *ashe*, tea).

In the “Plant Identification Chart for Creek Speakers,” Snow and Stans (2001) list *P. grandiflora*, *P. lutea*, and *P. rugelii* only under *sypeyv* and *wootaacheeke em oekekche*. There is apparently more about identification and use of the genus than the simple version given by Sturtevant (1955) indicates. Organisms that have uses older than cultural memory always have long and complex associations with people.

Snow and Stans (2001) illustrate *P. grandiflora* in their Plate 24, and call it *sypeyv*, with the English names “small one” and “candy root.” Snow wrote, “You find this plant in an open place on dry or damp land. Get four whole plants with the root attached. The thin stem is about a foot tall with small purple flowers, and the root is white. You use *sypeyv* for treatment to clean the body and to vomit. It is used in ‘on the wagon medicine’ as well.” In keeping with Snow’s comment that *sypeyv* cleans the body, large doses of *P. rugelii* are reported to act as a strong laxative.

The Choctaw used *P. lutea* (bog bachelor’s-button, candyweed, wild bachelor’s-button), calling it *kwonokashaipsa* [*kwonokasha ipsa*] (*kowaanakaasha*, little people, *impa*, eat it), as a poultice to treat swelling by infusing dried blossoms in hot water (Bushnell 1909). Florida’s other species with a recorded use is *P. polygama*. As with several species, it has been used to treat coughs. Both probably contain the saponin wintergreen.

John K. Small (1869–1938), the botanist from New York Botanical Garden who explored Florida during his winter breaks, was the first to recognize one endemic species as distinct. He called that herb *P. arenicola* in 1905. In the 1970s, Robert R. Smith and Daniel B. Ward at the University of Florida realized that, because of a legal technicality, the plants needed a new name. They commemorated this New Yorker’s keen observations by dubbing the plants *Polygala smallii*.

Urbanization in southern Florida has pushed *P. smallii* to the edge of extinction. The species was proposed for the Federal Endangered Plant List, and it became one of the first from the region to be listed in 1985. Because no one knew much about the plants, or why they were so restricted, several studies were initiated.

Pamela Krauss, while at Florida Atlantic University, discovered by the early 1980s that the species was restricted to small sandy spots in rockland pine flatwoods in Miami-Dade County. Apparently, the Broward County plants were extirpated by then. About the same time John Popenoe, then Director of Fairchild Tropical Garden, found the species in Martin County’s Jonathan Dickinson State Park. In the late 1990s George Gann rediscovered the plants in Martin and subsequently in nearby Palm Beach and St. Lucie Counties.

Even these northern populations reproduce erratically, and studies for the Florida Native Plant Society by Christine Lockhart are producing population data that will help future management of this highly endangered Florida endemic. One of the aspects of its biology that is a contributor to its spotty distribution is its isolation in “pockets” of sand within pinelands. Another of those aspects may be dispersal by ants.

Ant colonies have limited ranges, and that restricts where the seeds can be carried. To accomplish their dispersal, *Polygala* seeds have special “food-bodies” (elaiosomes). Those tiny structures attract these small foraging insects. Ants carry the seeds back to their nests, eat the food, and then discard the seeds outside. The seeds, having been put in a rich garbage heap with plenty of open space and reduced competition, germinate and provide new colonies. Perhaps our disruption of native ants with pesticides and alien introduced ants is showing us the “ripple-effect” of disturbing one small segment of the web of life.

We humans are incredibly arrogant and egocentric, and we tend to think that only big animals are important. Still, we can make fun of ourselves, and ants. There is a song *High Hopes* (1959) where, although everyone said it could not, an ant carries off a rubber-tree plant. So, never underestimate the importance of your neighbors.

### *Polygonatum*

(From Greek *polys*, many, *gonu*, knees, alluding to the many joints of the rhizome)

***Polygonatum biflorum*.** From Britton and Brown 1896.

*frassinella* (little ash, Italian 1551)

Ladder to Heaven (John Parkinson wrote in 1640, “Wee in English [call it] Salomon’s Scale most usually, but in some countries the people call it Ladder to Heaven, according to the Latine *scala coeli*, which was anciently known to the Apothecaries shoppes, from the forme of the stalke of leaves, one being set above another”)

*poligonia* (derived from the Greek *polygonaton*, Spanish 1557)

Salomans scale (Gerarde [1597] 1975); Solomon’s seal (translated from Latin *Sigillum solomonis*; used in English by 1526 in the *Grete Herball*); *Salomons segel* (Dutch 1549); *Salomonssiegel* (modern German); *sceau de Salomon* (French 1549); *sigillo di Salome* (modern Italian)

*scala caeli* (ladder to heaven, Turner said this was English in 1548 even though it is Latin)

*Weiswurtz* (white herb, German 1542)

***Polygonatum biflorum*** (two-flowered)

seal-wort [sealwort]

[great, King] Solomon's seal; *sceau de Salomon* (Solomon's seal, Quebec)

*utistugi'* (Cherokee)

According to the OED (1971), people in the Middle Ages (A.D. 500-ca. 1500) began calling European plants *sigillium Solomonis* (Solomon's seal). That name was said to be based on an even older history, going back to the time of the biblical King Solomon. Greek physician Dioscorides (fl. A.D. 40–80) called the plants *polygonaton* and wrote, "Spreading on the root helps cure wounds. Indeed, it also removes and aids facial blotches." Roman doctor Galen (A.D. 129–7200) recorded, "The root of polygonatum is spread on wounds. It is with it that they clear birthmarks [moles] from the face." In medieval times the plants were used to "seal" or "mend" wounds, sores, and especially bruises. Fuchs wrote in 1542, "Women today still wash and color their faces with Solomon's-seal." (Meyer et al. 1999).

Fuchs noted in 1542 that the pharmaceutical name for the plants in Germany was *Sigillium solomonis* (Meyer et al. 1999). Passage of time led to confusion and there arose three versions of why the plants were named after Solomon. One of the stories said that transverse sections of the rootstocks resembled a seal used by the biblical king. Another held that it was not the section but the leaf scars that looked like his seal. The third view held that it was because the root was good "to seal and close up green wounds" (OED 1971).

The Cherokee, Menomini, Meskwaki, Ojibwa, and Rappahannock used the American plants as medicine (King 1984, Moerman 1998). The Cherokee treated dysentery, breast diseases, carbuncles and other skin problems, leukorrhea, stomach problems, and lung diseases with the herbs (Hamel and Chiltoskey 1975). They also considered the root a mild tonic. The Menomini used the roots as an analgesic. The Menomini and Meskwaki put the root in an incense to revive unconscious people. The Ojibwa used the root as a physic and cough remedy. The Rappahannock treated cuts, bruises, and sores with the roots in a salve.

The Cherokee used the dried roots to make flour for bread (Hamel and Chiltoskey 1975). Young stems were also eaten like asparagus. Yanovsky (1936) and Fernald et al. (1958) say that several northern tribes used them in the same ways. The Ojibwa burned the roots as incense before going to bed (Moerman 1998).

***Polygonum***

(Greek *poly*, many, *gonum*, knees or bends, in reference to the many swollen nodes on the stems)

arssmerte (for *P. hydropiper*, by Turner in 1548)

*corriola bastarda* (false morning glory, Portuguese)

*glúineach* (having large knees, Gaelic)  
*Knöterich* (knotted, German)  
 knotgrass (from the knotted or jointed stem of *Polygonum aviculare*, in English by 1500)  
*lus an fhògair* (banishment herb, Gaelic for *P. hydropiper*)  
*renouée* (French)

***Polygonum demiflomm*** (compactly flowered)  
 denseflower knotweed (USA)  
 guinea hen bush (Bahamas)  
*herbe pou poule* (little chicken herb, Guadeloupe, Martinique)  
 John doctor (Bahamas)  
*lechuga* (lettuce, Guatemala)  
*piment vache* (cow pepper, Guadeloupe, Martinique)  
 snout smartweed (Texas)  
*yerba de hicotea* (turtle herb, the *jicotea* is a freshwater turtle, Taino, Puerto Rico)

***Polygonum hydropiperoides*** (resembling *P. hydropiper*)  
 American water pepper [water-pepper] (USA)  
*chillillo* (little chile, Valley of Mexico)  
*flor de chajutal* (hot flower, Guatemala)  
 swamp smartweed (Florida)  
 tasteless knotweed (a misnomer; the plants are spicy when chewed, USA)

***Polygonum punctatum*** (dotted, meaning the tepals)  
*canilla de pava* (strong turkey, Guatemala)  
*chile de perro* (dog's chile, Costa Rica); [*chillillo*] *de perro* (little [dog's] chile, Guatemala); *chillillo rojo* (red chile, Veracruz); *piment vache* (cow pepper, Guadeloupe, Martinique)  
*curage* (cleansing, French, Houma, Louisiana)  
*ojigimin* (fisher-berry, Ojibwa)  
*rorisowa* (*kori*, chile or *Capsicum annuum*, Tarahumara, Chihuahua)  
 [American, dotted, water] smartweed (Florida, Texas, Bahamas, Puerto Rico)

***Polygonum.*** *Polygonum densiflorum* .  
*Polygonum hydropiperoides* . Both  
 from Institute of Food and Agricultural  
 Sciences.

*yerba de burro* (donkey's herb, Dominican Republic); *yerba de caiman* (caiman's herb); *yerba de hicotea* [*hycotea*, *jicotea*] (turtle herb, *thejicotea* is a freshwater turtle, Taino, Dominican Republic, Puerto Rico)

Most of *Polygonum* is referred to as "smartweed." Diggs et al. (1999) cite a comment by Kirkpatrick (1992) suggesting that the name was derived from the tendency of the sap to "smart" (burn) when it touched the skin. However, historical data support a slight modification of that view. "Smartweed" was applied to *P. hydropiper* by 1787. In that year, W.H.Marshall, writing on the rural economy of Norfolk, said, "*Smartweed*, biting and pale-flowered persicarias; arsmart." Indeed, the OED lists "arsesmart" as the common name for "smartweed." So, Kirkpatrick had the right idea, but the wrong part of the body.

Several species have a peppery taste, like *P. hydropiperoides* and its namesake *P. hydropiper* (water pepper). Indeed, Dutch herbalist Rembert Dodoens simply called the second species *Hydropiper* in 1554, surely reflecting its use in seasoning food. Fernald et al. (1958) noted that application for it and several relatives. The practice is problematical because some people develop contact dermatitis from the plants (Foster and Duke 1990).

There appear to be no records of people in the Americas using *P. densiflorum*, but Hawaiians use an infusion of the plants to purify the blood (Moerman 1998). Perhaps that species is used like some of the others in the New World although there are no records to

support that. In the Bahamas, the root of *P. densiflorum* is crushed and inhaled to relieve headache (Higgs 1969).

The earliest association of *Polygonum* with Florida people was *P. hydropiperoides* in pre-Columbian Glades coprolites from Fort Center on Lake Okeechobee (Hogan 1978). *Polygonum hydropiperoides* contains tannins, rutin (3% in the leaves), quercetin, and kaempferol (Hocking 1997). It has been used to stop intestinal and uterine hemorrhage, for strangury (slow, painful urination), and as a stimulant. In Brazil, *P. hydropiperoides* is considered diuretic, and an emmenagogue, and used as a treatment for piles. It is used to promote conception in Mexico (Ford 1975, Hocking 1997, Vasquez and Jácome 1997).

Among the Houma, a decoction of *P. punctatum* roots was used to treat pains and swelling in the legs and joints (Speck 1941). Farther north, the Ojibwa took a decoction of leaves and flowers for stomach pain, and the Iroquois made a compound medicine for “loss of senses during menses” (Moerman 1998). The Tarahumara of northwestern Mexico used the plants as a fish poison (Pennington 1958). They bundled the plants, crushed them, and put them in large baskets, which they dipped into water until the water turned green. According to Pennington (1958), “fish rise to the surface almost immediately.” Tarahumara also added young leaves to their corn dish *esquiate* for a spicy flavor.

In Hispaniola, *P. punctatum* and other plants in the genus are rubefacients when crushed; they are stimulant, astringent, diuretic, emmenagogue, anthelmintic, and antiarthritic. On that island, the species is used against urinary and gallbladder problems, and to treat hemorrhoids, intermittent fever, and malignant sores (Liogier 1974). Several of the common names mention dogs. Those are indications that the herb is wild, but perhaps also indicates that the plant has been used to treat mange (*jiote*, from *xiotl*, Nahuatl) in dogs (Morton 1981).

Europeans were familiar with *Polygonum* when they arrived in the New World. They had learned that the small seeds from weedy species like *P. aviculare* could be harvested and used, at least as a starvation diet (Fernald et al. 1958). Indigenous Americans also used *P. erectum* in the same way. Indeed, there is evidence they cultivated that species for food (Smith 1992). More recently, the seeds of at least *P. hydropiperoides* have been promoted as a protein source (Boyd 1968, Boyd and McGinty 1981).

### *Polyporus*

(The genus was named by E.M.Fries, 1794–1878, from Greek *poly*, many, and Latin *poms*, small openings)

false truffle (USA)

*okipen* (earth tuber, Virginia Algonquian)

*turma* (truffle, name used by Fontaneda [1575] 1944)

When Hernando Descalante Fontaneda was rescued from his captivity among the Calusas of southern Florida, he returned to Spain and wrote an account of his time among those people (Fontaneda [1575] 1944). One of the few “plants” he mentioned was a root eaten by the Floridians. In speaking of people who lived on the *laguna de mayaimi* (Lake

Okeechobee), he wrote, “y sobre esta laguna que cor re por en medio de la tier r a dentro tiene muchos pueblos aunque son de treynta i quarenta vso. y otros tantos lugares tienen pan de rraises ques la comida ordinaria la mar parte del tiempo, aunque por caso de la laguna que crese mucho que no alcansan estas rraises por estorbo de la mucha Agua y ansi dejan de comer Algun tienpo este pan pescado mucho y muy bueno, otras Rayses a manera de turmas de las de Aca duses.”

Buckingham Smith translated this as follows: “On this lake, which lies in the midst of the country, are many towns, of thirty or forty inhabitants each; and as many more places there are. They have bread of roots [*Smilax*], which is their common food the greater part of the time; and because of the lake, which rises in some seasons so high that the roots cannot be reached in consequence of the water, they are for some time without eating this bread. Fish is plenty and very good. There is another root, like the truffle over here, which is sweet.”

In spite of Fontaneda’s comparison of the second root to truffles, Smith interpreted the *turma* as being *Apios americana*. Smith had apparently never been in swamps where *Apios* grows, or he would not have selected that species. If the water was too high for their common food (*Smilax*), it was certainly too deep to gather *Apios*. Elsewhere I have made the argument that the “bread” noted by Fontaneda was the carpophore of *Polyporus* (Austin 1980). Gerard (1907) found the product also being eaten by the Virginia Algonquians.

### *Polypremum*

(From Greek *polypremnos*, many-stemmed)

*Polypremum procumbens*. a. Flowering branch, b. Twig with

flower, c. Flower, from above, d.  
 Flower, longitudinally dissected, e.  
 Pistil, f. Floral diagram, g. Fruit within  
 calyx, h. Fruit. *Drawn by Priscilia  
 Fawcett. From Correll and Correll  
 1982.*

***Polypremum procumbens*** (prostrate or lying on the ground, meaning the  
 stems)  
 rust-weed

*Polypremum* was named by Linnaeus in 1753. The genus contains a single species in the warm parts of the Americas. Although few disagree that it a distinct species, there is contention regarding its familial relationships (Cronquist 1981, Mabberley 1997).

The plant is used as a remedy for metritis (uterus inflammation) in El Salvador (Von Reis 1973).

### ***Polystichum***

(From Greek *polys*, many, and *stichos*, rows, alluding to the sori of some species being in ranks)

***Polystichum acrostichoides*** (resembling *Acrostichum*, which see)  
 bear's bed (derived from the Cherokee name); *yana utseta* (the bear lies on it, Cherokee)

canker-brake ("canker" came from Old Northern French *cancre*, and appeared in English by about A.D. 1000; the word is cognate with "cancer"; historically, the disease was a malady of the mouth; "brake" is akin to Old Swedish *braekne*, fern)

Christmas fern

dagger fern (from the shape of the leaflets)

*fougère à faucilles* (sickle fern, Quebec)

shield fern

*tapasi moso'here* (flower on [branch grows] rough, Catawba; not distinguished from *Pleopeltis*, which see)

No one had to explain the reason for calling the plants "Christmas fern" when I learned it on a college course field trip in the early 1960s. Around us the woodland was bleak from the winter cold, with bare trees, dead and fallen leaves on the ground, and ice covering the surface of the creek. Tucked in a hillside crevice of rich organic soil was this single green plant. From the name, I surmised that people had used this evergreen plant in decorations at Christmas time. I was correct, but the fern appeared in the literature under that name only in 1878. People of North America probably began using the name much earlier.

*Polystichum* is a genus with four European species (Mabberley 1997). While Kartesz (1994) recognized 24 species and 2 named hybrids in the United States and Canada, only 15 were included in the *Flora of North America* (Wagner 1993).

The German physician Albrecht W. Roth (1757–1834) created the genus *Polystichum* in 1799 for a species in his country. In doing that he moved a species Linnaeus called *Polypodium lonchitis* into his new genus. That species is now known to range from Europe to western North America, with isolated localities around the Great Lakes, Newfoundland, and Nova Scotia.

Later, André Michaux discovered the most common species in eastern North America in 1803, and they were given their modern name in 1834. Unlike some ferns, these have a comparatively rich history of uses.

Hamel and Chiltosky (1975) confirm that the Cherokee ate the fiddleheads. We question that because neither Hedrick (1919) nor Fernald et al. (1958) list the plants.

The more common application of the plants was as medicine. The Cherokee used the plants as an emetic, and to treat rheumatism, chills, fever, stomachache, bowel problems, and toothache (Hamel and Chiltoskey 1975). The Iroquois treated cramps, convulsions, diarrhea, fever, and rheumatism, used it as a blood purifier, and as an emetic for dyspepsia; it was taken before and after birth to clean the womb. The Malecite and Micmac chewed roots to relieve hoarseness (Moerman 1998).

### *Pontederia*

(With this name, Linnaeus commemorated Italian physician Guilio Pontedera, 1688–1757, professor at Padua and also the prefect of the Botanical Garden of Padua from 1719 to 1757)

***Pontederia cordata*** (heart-shaped, the leaves)

*hicaknâ:blo:cî* [*hitcakanablotci*] (*hicakna*, feraltaro, *a:hi*, replica, *lo:ci*, black, Mikasuki; see *Sagittaria* for more on etymology); *hikacha nabe* (*hicakna*, feral-taro, *a: hi*, replica, Mikasuki)

*hishi shafuha* (*hesse*, leaf, *cofokne*, pointed, Creek)

pickerel [pike]-weed (USA)

*wampee* (it is white, Shawnee); *wompi* (Massachusetts)

Linnaeus ([1753] 1957) knew this species from publications by several previous authors before he studied the living plants at the *Hortus Cliffortianus*. He knew only one, but there are now five American species in *Pontederia* (Mabberley 1997).

Although Sturtevant (1955) was told this herb was useless, seeds may be eaten directly from the plant, boiled as cereal, or dried for future use (Fernald et al. 1958). Dried seeds were ground and made into flour for making bread (Morton 1968b).

Farther north, the Malechite, Micmac, and Montagnais people used the plants for medicine. The

***Pontederia cordata*.** a. Habit, b. Flower, c. Revolute-coiled perianth after flowering. *Drawn by Vivian Frazier. From Correll and Correll 1972.*

Malechite of New Brunswick and Micmac of Nova Scotia used *Pontederia* as a contraceptive (Moerman 1998). The Montagnais of eastern Quebec and Labrador made a treatment for “illness in general” from the herbs.

### ***Populus***

(Classical Latin name for the genus, maybe referring to people; or perhaps from Greek *paipaloo*, shutter, or *paipapalloomai*, tremble, vibrate)

***Populus deltoides***. From Sargent 1905.

*álamo* (based on *ala*, wing, in both Spanish and Portuguese; presumably from a resemblance of the fluttering leaves to wings on birds)

*amocholhe* (Delaware)

*crintheann* (trembling, Gaelic)

*eadha* (Gaelic)

poplar (from Latin *populus*, spelled “popler” by Turner [1548] 1965); *chopo* (from Latin *populus*, Spanish); *choupo* (Portuguese); *Pappel* (German); *pappel* [*popel*] (Dutch); *peuple* (French); *pioppo* (Italian); *poppel* (Norwegian, Swedish) *squejóna* (Onondaga)

***Populus deltoides*** (deltoid or triangular, from the outline of the leaf)

*álamo* (cottonwood, Texas); *alamo* cottonwood (a redundant name)

*ashumbala* [*shumbala*] (Choctaw); *hashoomala* [*hasho'mala*, *hashoomala'*, *ashomala*, *ashoomala*, *ashoomala'*] (questionably from *hasha*, leaf, *im*, its, *ala* =?, Chickasaw)

*ba'-k'a hi* (a sacred tree, used in rites, Osage); *chan ya'hu* (*chan*, tree, *ya'hu*, peel off, in reference to their use of the bark as food for horses, Dakota); *maa zhon* (*maa*, cotton, *zhon*, tree, OmahaPonca); *wdga chan* (*wága*, take off, *chan*, tree, Dakota)

[eastern, southern, yellow] cottonwood (“cotton,” originally the wool surrounding the seeds of *Gossypium*, brought into English about A.D. 1300 from French *colon*, which in turn came from Arabic *al-qoton*, with the deletion of the article. Lewis and Clark called the trees “Cotton Timber” at their winter quarters with the Mandan in 1804. Although the OED 1971 says that “cotton” was combined with “wood” about 1823 to indicate the cottony fluff around the seeds of these trees, “cottonwood” was also used in the Lewis and Clark journal of 1804.)

*ete hesha kaklahashe* (noisy leaf tree; from *ete*, tree, *hissi*, leaf, *chashahachi*, rattle, Choctaw)

*hecelwv* [*hecelwv*] (“poplar,” Muskogee; apparently not cognate with Creek *wtahkv*)

*itti tohbi'* (*itti'*, tree, *tohbi'*, white, Chickasaw)

*laird* (from *Her*, to bind, related to Latin *ligare*; some books specifically mention fascicles or bundles, perhaps of wood, Quebec)

*natakaaru* (Pawnee)

*peuplier* (from Old French *peuple*, still in use by some country people, from Latin *populus*, dated ca. 1170, Quebec)

[Carolina-, necklace-, water-] poplar

*putitu kayudi* (Ofo)

*tai* [*tay*] (Atakapa)

*taftahkv*, [*tarrahkv*, *tartahkv*, *tvrtahkv*, *wtahketaftu'hkv*, *taftahkv*] (Creek); *taftahká* [*taftahká*] (Kosati)

*ya-hee-hwai* [*ä'hi'ñ*, *ä-heeñ*] (*a-heen*, principal, *hwai*, tree, Kiowa)

***Populus heterophylla*** (variable leaves)

[black, swamp] cottonwood

downy poplar

According to Greek legend, Hercules was wearing a crown of poplar twigs when he returned from Hades after vanquishing Cerberus, the guardian hell-hound (Baumann 1993). The Greek tree forming his crown was the white poplar (*Populus alba*), and the twocolored leaves symbolized respect for the Chthonian deities. The dark side of the leaf represented the Underworld, and the light side the living. This tree became the *arbor populi* (tree of the people) to the Romans, and it was used to decorate public places such as the *Piazza Poppolo* in Rome (Hocking 1997). Just how much that Greek association with the Underworld affected different cultures is partly indicated by the dominance of their word in languages throughout Western Europe. The species is now cultivated as far north as Norway and Sweden where it is known as *sølvpoppel* (silver poplar).

In a parallel view, people of the Missouri River region also held the cottonwood as sacred but surely for different reasons. The Sacred Pole of the Omaha was made from cottonwood, and the bark was used as fuel for roasting the clays to make paints for heraldic and symbolic paintings on their bodies (Gilmore 1919).

Many people throughout the range of *Populus* in North America have eaten the inner bark (Moerman 1998). The Cheyenne, Blackfoot, and Dakota ate the inner bark and sap, particularly in the spring (Gilmore 1919, Moerman 1998). Other people eating various parts of *P. deltoides* include the Coeur d'Alene, Flathead, Kutenai, Montana, Ojibwa, Omaha, Pawnee, Pima, and Ponca (King 1984, Moerman 1998). In the southwestern United States, many people ate *P. deltoides* ssp. *wislizeni* (Moerman 1998).

At least four dye colors were obtained from *P. deltoides*. The Cheyenne used the buds to make green, brown, and red dyes, although the methods are not given (Moerman 1998). Missouri River people also used the buds to make yellow dyes (Gilmore 1919). Tull (1999) indicates that yellow may be obtained with alum, tin, or chrome as mordants. Green results from copper or iron mordants.

Wood from *Populus* was an important resource throughout its range. Swanton (1946) found the southeastern tribes making their largest canoes of poplar. Southeastern people also used the wood to make stools, doors of houses, and fire sticks. *Populus deltoides* wood more recently has been used for paper pulp, cases and crates, tubs and pails, excelsior, veneer for plywood, musical instruments, dairy and poultry supplies, laundry appliances, and fuel (Vines 1977).

There are numerous records of "poplar" being used among indigenous people for a variety of medical treatments. Many of those references are impossible to pin to a species. Probably Duke et al. (2002) have made the best choice by listing them all under the name "popular" (*Populus* spp.). Caution is advised, however, because reports of "popular" include both *Liriodendron* and *Nyssa*. Since the *populus* species all contain salicin, it seems likely that they were used similarly in medicines.

The *Populus deltoides* was used by several south-eastern tribes and by some in the northeast. The Catawba used an infusion of the bark, along with wild cherry and dogwood to treat expectant mothers (Vogel 1970). The Chickasaw boiled cottonwood and willow roots to make a drink to treat dysentery and fever (Swanton 1928a). The Choctaw boiled leaves and bark to treat wounds and made a combination of stems, leaves, and bark to

cure snakebite (Bushnell 1909). The Creeks used a decoction of cottonwood to treat sprains and fractures and a decoction of roots as a remedy for dropsy (Swanton 1928a, Taylor 1940). The Delaware combined cottonwood with black haw and wild plum bark to make a woman's medicine (Moerman 1998). The Iroquois made a vermifuge of the plants (Hocking 1997). The Ojibwa used the cottonwood in two distinct ways. Buds were stewed with bear fat and used to treat earache, while the cotton from fruits was used as a absorbent on open sores (Vogel 1970).

Porcher (1863) wrote of *P. heterophylla*, "Upon examining the excrescences caused by an insect in large numbers on the leaves of the cotton-wood tree ... I find them possessed of great bitterness, and suggest an examination into their tonic properties." No other indication has been found of others following this lead. However, Porcher (1863) recommended using *P. deltoides* extract as a substitute for quinine in treating what was called at the time as "swamp fever," now known as malaria (Hocking 1997).

Early in its history another North American *Populus* became confused with tropical *Bursera*. Because of that confusion, *P. balsamifera* became known as *tacamahaca* (Vogel 1970, Bremness 1994). That Aztec name was originally applied to *Bursera* (see *Bursera*: Gumbo Limbo), but the literature on common names now largely associates it with *Populus*. In another oddity, the European *P. alba* became official in the U.S. Pharmacopoeia between 1895 and 1936 as a source of salicin, but native North American species were listed (Vogel 1970). To fill that gap, Eclectic physicians recommended several native *Populus* (Culbreth 1910, Felter 1922).

### *Prenanthes*

(From Greek, *prenes*, drooping, and *anthe*, flower)

*Haselattiach* (hare's lettuce, German)  
*lattuga montana* (mountain lettuce, Italian)  
*prenanthé* (French)

***Prenanthes serpentina*** (old name for various plants used to treat snakebite)  
 cancer weed

[white] canker weed [cankerweed, canker-root] ("canker" came from Old Northern French *cancre*, and appeared in English by about A.D. 1000; the word is cognate with "cancer"; historically, the disease was a malady of the mouth, perhaps a reference to thrush or *Candida* infection)

*dado'cabodji'bik* (milk root, for *P. alba*, Ojibwa)

DeWitt snakeroot; rattlesnake root; snake-gentain; snakeweed (names given alluding to use against snakebite)

drop flower (it is not clear if this English name gave rise to the genus created by Linnaeus in 1753, or vice versa)

earthgall [gall of the earth] (used since about A.D. 1000 for *centaurium pulchellum*, alluding to it being bitter like bile; later applied to *Prenanthes*)

*laitue blanc* (white lettuce, Quebec); *weisser Lattich* (white lettuce, German); white lettuce

[ivy, joy] leaf

lion's foot (used for a *Helleborus*, Ranunculaceae, by Turner in 1538; and for *Alchemilla*, Rosaceae, by 1610; later applied to other plants); *ped d'leon* (lion's foot, French)

milkweed (usually applied to *Asclepias*, but also to others with white latex)

Two of the *Prenanthes* that Linnaeus ([1753] 1957) knew were from the New World, and the other five were from Europe and Siberia. However, it was not until 1814, when Frederick Pursh published his *Flora America Septentrionale*, that *P. serpentaria* was added to the list. Now there are 30 species known from the north temperate region, and the European plants have been reduced to a single species (Mabberley 1997).

This was one of the many plants used by the indigenous tribes to relieve the bites of snakes and other venomous animals. There are many more poisonous snake species in eastern North America than in Europe, and the settlers were quick to rely on the local remedies for these problems. Accounts are common in the literature of the time of a person being bitten by a reptile and recovering after chewing, ingesting, and/or applying a poultice of some plant.

Writing in 1728, William Byrd gave a typical account of the time. Not only were his observations dubious, but he also clearly had no regard for the safety of his dogs. He wrote: "The rattle-snake, has an utter antipathy to this plant, insomuch that if you smear your hands with they juice of it, you may handle the viper safely. Thus much I can say of my own experience, that once in July, when these snakes are in their greatest vigor, I besmear'd a dog's nose with the powder of this root, and made him trample on a large snake several times, which, however, was so far from biting him, that it perfectly sicken'd at the dog's approach, and turn'd its head away from him with the utmost aversion" (Coffey 1993).

James Adair listed several snakebite plants, including *P. serpentaria*, in a book about his trading among the Creeks along the Mississippi River in 1775. Prince Maximilian listed as a remedy a plant called "lion's heart" among the Delaware in the 1830s (Vogel 1970).

In the eastern states, several tribes used *Prenanthes* as a snakebite remedy. At least *P. alba*, *P. altissima*, *P. aspera*, *P. serpentaria*, and *P. trifoliata* were utilized (Moreman 1998). These all went under the name "snakeroot," "lion's foot," or "gall of the earth."

Northeastern tribes certainly applied *P. alba*, and there are records of both the Iroquois and Ojibwa using it on snakebite (Densmore 1928, Moerman 1998). The Iroquois also used *P. altissima* and *P. trifoliata* (Moerman 1998).

However, indigenous people did not confine the plant to those uses. In the south, the Choctaw used *P. virgata* (reported as *Nabalus asper*, and *P. aspera*, corrected by Joanne Birch) as an anodyne and as a diuretic, and for other problems (Campbell 1951). The Cherokee used both *P. serpentaria* and *P. trifoliata* roots in stomachache medicine (Hamel and Chiltoskey 1975). The Cherokee also cooked and ate the leaves of these two herbs.

Porcher (1863) did not say much about *Prenanthes*. He wrote simply of *P. alba*, “The root is excessively bitter; it is used in domestic practice in this state as a tonic. I would invite further examination.”

Millspaugh (1892), on the other hand, had a lot to say about the plants. First, he complained, “This botanically difficult species...includes in itself what were once considered to be 17 distinct species and varieties; and affords an interminable field of work for a botanist of Rafinesquian tendencies.” He continued, “As Gall of the Earth, it has been known in domestic practice from an early date, and is said to be an excellent antidote to the bite of the rattlesnake and other poisonous serpents—one who searches through the domestic literature of medicinal plants, wonders why the bite of snakes ever has a chance to prove fatal.” He recommended the species for relieving dysentery, anemic diarrhea, and as a stomach tonic. Hocking (1997) added that the plants were used as a bitter tonic, an astringent, and “to relieve hypertension in Negroes.” The genus is not listed by Bremness (1994), Bown (1995), or Duke et al. (2002).

Millspaugh (1892) recorded that chemical studies of the plants had found resins, tannins, gums, and waxes. Hocking (1997) agreed that they contained tannin, and that it was known as *Herba Nabali serpentariae* among the homeopaths. The Latin pharmaceutical name was based on the old generic name *Nabalus*. There were no papers listed on the genus in either PubMed or AGRICOLA in January 2003.

### *Prunus*

(Classical Latin name of the plum, *P. xdomestica*; Greek *proumne*)

#### *Prunus americana* (of America)

##### *ciruela* (Mexico)

*kande* (*kande-hi*, plum tree, Omaha-Ponca); *kante* (*kante-hu*, plum tree, Dakota); *kon'-dse xo-dse* (*kon'-dse*, plum, *xo-dse*, gray, Osage); *kantsh* (*kantsh-hu*, plum tree, Winnebago)

***Prunus*.** *Prunus americana* (top left). *Prunus angustifolia* (upper middle left). *Prunus caroliniana* (lower middle left). *Prunus serotina* (bottom left). All from Sargent 1905. *Prunus myrtifolia* (right), a. Flowering branch, b. Lateral spike at early stage of expansion, c. Staminate flower, the pistillode longitudinally dissected, d. Perfect flower, front-side view. e. Perfect flower, longitudinally dissected, f. Floral diagram of perfect flower, g. Fruits. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*kwanunsdi?i* (Cherokee)

*niwaharit* (*niwaharit-nahaapi*, plum tree, Pawnee)

*pank-ai-da-lo* (sour plum, Kiowa)

[August, Canadian, goose, hog, horse, native, river, thorn, wild] plum  
("plum" from Old English *plumé*, which in turn was derived from Latin

*prunus*); Potawatomi plum (a tribe in Michigan; the plum was introduced into Utah); red and yellow plumb (used by Williams [1837] 1962); [American, red, wild yellow] plum (Asa Gray 1875 distinguished red and yellow plums)

*poskam* (Strachey in [1612] 1953 wrote *poskamatk*; Siebert 1975 found cognates among several other Algonquian languages, some of which were transfers after contact with the imported European fruits; the Shawnee say *poʔkama* for the peach, *Prunus persica*, and used the diminutive *poʔkamaTa* for plum; the Ojibwa say *pokkitons*, but apply it to the pear, *Pyrus communis*); *bu'gesana'tig* (Ojibwa)

*pvkánvhe* (Muskogee)

*sipuamantican* (Delaware)

sloe (plum, from Old English *sláh*, used in English since about A.D. 725, related to Frisian *slé*, Dutch *slee*, German *Schlehe*)

*tischo* (Onondaga)

*turi-'tcine* (fruit bitter, Catawba)

***Prunus angustifolia*** (narrow-leaved)

*akōnt atcūti* (*akōnti*, peach, *atcūti*, red, Ofo)

Chickasaw [Chicasa] plum ("Chickasaw," the name of a Muskogean tribe, appeared in English by 1674; used for the plum by Andre Michaux 1802)

*contai* (Quapaw)

*eco empykany* (*eco*, deer, *em*, its, *pvkany*, peach, Creek)

*icho intakkosàwwa* [*ichintakkosàwwa*] (*icho*, deer, *im-*, its, *takkola*, plum, *sawwa*, small, Alabama); *isi intakkonlushi* [*isi takkonlushi*] (*isi*, deer, *in*, its, *takalo*, peach, *oshi*, small, Choctaw); *takkolsalbd* (*takkolá*, peach, *salbá*, maybe cognate with Alabama *sawwa*, small, Koasati)

*iti alikchi* [*italikchi*] (*iti*, tree, *alikchi*, doctor, Choctaw; an axiom of the tribe was never to kill a cherry tree; considered the best medicine for young girls)

*kwah noon:* ' *sdeʔee* (Cherokee)

mountain cherry

[sand, sandhill, Indian] plum

*stiiñki* (Biloxi)

*takkonlushi* [*takkon lushi*] (*takkon*, originally plum, now peach, *oshi*, small, Choctaw); *takkoosàwwa* [*takkosàwwa*, *takkosáwwa*] (*takkola*, plum, *sawwa*, small, Chickasaw); *takoloshi'* (Chickasaw); *takoloshi'* *imilhlha'* (*takoloshi*, plum, *imilhlha'*, wild, Chickasaw)

***Prunus caroliniana*** (from Carolina)

[American, Carolina] cherry or laurel-cherry [laurelcherry] ("laurel-cherry" was in use by 1789; the modifiers distinguish the New World from the Asian species)

cherry laurel (in English by 1664; the namesake, *Prunus laurocerasus* was introduced into Europe in 1576 from Turkey, according to Linnaeus;

Old World plants were used to make “cherry-laurel water,” a watery solution of the volatile oils from the plant containing prussic acid)

*ittokchakkosi* (*itto*, tree, *okchakko*, blue-green, *osi*, small, Alabama)

mock-[wild-]orange

wild-peach

***Prunus geniculata*** (referring to nodes, sometimes resembling knees, the stems being zigzag)

[Harper’s, scrub] plum

***Prunus myrtifolia*** (with leaves like myrtle, *Myrtus communis*)

*almendrillo* [*almendrito*] (little almond, Cuba, Dominican Republic, Puerto Rico); *almendro* (almond, Venezuela); *amandier à petite feuilles* (little-leaf almond, Haiti); *amandier des bois* (Martinique)

ants-wood (Jamaica)

cassada-wood [wild cassada, wild cassava] (comparing it with “cassava” [*Manihot*], Jamaica)

*cuajani hembra* (female *cuajani*; a river in the Dominican Republic has the Taino name *cuaja*, Cuba); *cuajanincillo* (little *cuajani*, Cuba)

*durasnero de monte* (wild peach, Brazil)

*la mandit* [*le mongier*] (the almond, Haiti)

*marmelo bravo* [*do mat to*] (wild quince, *Cydonia oblonga*, Brazil); *membrillo* [*membrillito*] (little quince, Dominican Republic)

myrtle laurel-cherry (USA); West Indian [laurel] cherry (USA, Bahamas)

*noyou* (almond, Guadeloupe; a name also applied to *Merremia dissecta*)

*polo de hacha* (ax tree, Dominican Republic) *virarú* (maybe from *virar*, leaning to one side, Brazil)

*warimiaballi* (*warimia*, is *Tapirira guianensis* in the Anacardiaceae, *balli*, resembling, Arawak, Suriname)

*yaya boba* (crazy *yaya*, the word *yaya* is surely Taino as it appears in several plant names, Dominican Republic)

***Prunus serotina*** (late-ripening)

*aguasique* (Pima Bajo)

*capulin* [*capolin*, *capuli*] (Náhuatl, Texas, Sonora to Veracruz and Chiapas, Guatemala)

*cereso* [*cerezo*, *cereza*] (Chiapas, Guatemala); *cerises d’atomne* (autumn cherry, Quebec)

[cabinet, mountain, rum, southwestern, whisky, wild] cherry or black-cherry [blackcherry] (“cherry” was derived in the 1300s from Old English *ceris*, which was taken from Latin *cerasus*’, cognates are Spanish *cereza*, Portuguese *cereja*, French *cerise*, German *Kirsche*, and Dutch *kers*; Greek *kerasos* is related)

[southwestern] choke-cherry [chokecherry, choke cherry] (a name applied to both *P. serotina* and *P. virginiana*, dating from about 1796 in the northeastern United States; the name refers to the astringent fruits)

*detzé* [detzé] (Otomí, Veracruz)

*gthon'pa hi* [gthon-pa hiu] (Osage)

*ikwe'mic* (Ojibwa); *okwe'minun* (grubworm berry, Potawatomi)

*ittó fotóhka* (*ittó*, tree, *fotóhka*, smells decayed, Koasati); *okóofa* [*okwaafa*, *okwáofa*, *okoofo*] (Alabama)

*ittobaksa* (*itto*, tree, *baksa*, thread, twine, Alabama; cf. also *Tilid*); *ittotalikcho* (*itto*, tree, *tafkcho*, rope, Alabama; identity doubtful)

*jeco* (Guarijío, Sonora)

*kona ha go* (*konawv*, bead, *hayetv*, to make, Creek)

*taunday* (Zapotec, Oaxaca) 'to *fvmpe* [*tofv'mpe*, *tofompa*, *tofámbi*] (*eto*, tree, *fvmpe*, cherry, Creek, Muskogee; cf. Simmons [1822] 1973)

*tup* (Quiché, Guatemala)

*usábi* (Tarahumara, Chihuahua)

*xeugua* (Michoacán)

***Pmnus umbellata*** (inflorescence branches resembling the ribs of an umbrella)

[flatwoods, hog] plum

[black] sloe [of the South]

Like other youngsters in western Kentucky, I grew up nibbling the fruits of *Prunus serotina*. Although they are somewhat bitter, to a boy they were pleasant, and helped slake thirst during a hard day spent exploring the woods and fields. The more sinister side of the plants was completely unknown until a neighbor's horse decided to sample a wilted branch. Although I was not yet a teenager, the vivid image of that dying animal is still burned in my memory. Later, I learned that it was the release of hydrocyanic or prussic acid (cyanide) that killed the poor creature. My friends and I became more cautious of the fruits, even though our reading about them revealed that they were a significant food to indigenous Americans, and the bark was one of their important medicines.

Many years later I tried the fruits of *capulin* in Lima, Peru. All my agriculturist colleagues at the *Centra Internacional de la Papa* there could tell me was that the fruit was an important food in their country, and that it was *una cereza peruana* (a Peruvian cherry). Eventually, I learned that the drupes I ate were simply a larger-fruited subspecies of what had been a part of my childhood diet.

Some 17 of the more than 200 species of *Prunus* grow in Europe (Mabberley 1997). Thus, Europeans brought a variety of common names into the languages they introduced into the New World. As an example, some names of Old World *Prunus* in Spanish are *albaricoque* (for *P. armeniaca*, the apricot), *cerezo de monte* (for *P. avium*, the wild-cherry), *ciruelo* (for *P. ×domestica*, the plum), *almendro* (for *P. dulcis*, the almond), and *melocoton* (for *P. persica*, the peach). A similar list could be given for other European languages.

When explorers and immigrants arrived in the New World, they found indigenous people using a number of native species. Seven of those grow in Florida; four native species are called “plums” and three are “cherries.”

Originally, the name “plum” meant only *P. ×domestica* and dates in English to about A.D. 700. That word was derived from Old Low German *pluma*, which came from Latin *prunus*. The same Latin word or its alternate declension *prunum* also gave us the English word “prune” about A.D. 1345, and its cognate *prugna* in Italian. In the 1700s and 1800s, some considered plums to be genus *Cerasus*, while cherries were *Padus*. However, even that nomenclature is confused because the Greeks used the word *kerasos* for the Old World bird-cherry *Prunus avium*. Theo phrastus (372–287 B.C.) used *Padus* (from Greek *pados* or *pedos*) for a cherry whose timber was used for axles.

According to historic usage, plums are usually larger than cherries, have a bloom or whitish wax on the skin, a somewhat flat pointed stone, and sweet pulp (OED 1971, Davidson 1999). Traditionally, a “cherry” has smaller fruits, no bloom on the skin, a rounded stone, and the pulp may be sweet, sour, or even bitter. The basis of the concept for “cherry” is *P. avium* or *P. cerasus*. However, in practice, usage breaks down, and *P. angustifolia* is called both a plum and a cherry. *Prunus angustifolia*, *P. americana*, *P. geniculata*, and *P. umbellata* are “plums”; alternately, *P. caroliniana*, *P. myrtifolia*, and *P. serotina* are “cherries.”

Although Cortez’s *conquistadores* had eaten *Prunus* in Mexico in 1519, it was the mid-1700s before the Florida species were named. Linnaeus knew only *P. virginiana* when he published *Species Plantarum* in 1753, and it had been discussed by Leonard Plukenet in 1696, Mark Catesby in 1731–1732, and IF. Gronovius in 1739–1743.

However, *Prunus* was first recorded in what today is the United States by the de Soto expedition. The Spanish found the plants near what is now New Madrid, Missouri, in 1540 or 1541, and noted that the Chickasaw were using them for food (Hedrick 1919). Those plums were surely what Varner and Varner translated as “dried fruit” from Garcilasco De La Vega ([1605] 1962). André Michaux tried to commemorate that important association between that tribe and the fruits by calling the trees *P. chिकासа* in 1802, but Humphery Marshall had already named them *P. angustifolia* in 1785. Not only did the people along the Mississippi eat the fruits, the Ozark BluffDwellers of Arkansas used the seeds to make beads (Gilmore 1931).

*Prunus angustifolia* grows from Florida through the eastern two thirds of Texas, and north to Missouri, Kentucky, and east to New Jersey and Maryland. Fernald (1950) said that it occurred elsewhere, “as a relic of cultivation.” Bartram ([1791] 1958) never saw them in the wild but always in deserted Creek villages. He speculated, “I suppose it to have been brought from the S.W. beyond the Mississippi, by the Chicasaws.” Maybe that comment is why Harrar and Harrar (1946) and Little (1979) thought that the original range of *P. angustifolia* might have been central Texas and Oklahoma, but that the trees were early and widely spread by indigenous tribes.

The fruits were favored by the Chickasaws as noted by the common name. Diggs et al. (1999) record that “Native Americans” dried fruits on hot rocks so they could be stored for future use. Otherwise, Moerman (1998) listed only the Comanche as using the fruits as food, both fresh and dried. Yanovsky (1936) and Hudson (1976) wrote that all southeastern tribes ate plums of all kinds.

*Prunus americana* ranges from Florida to northern Arizona and New Mexico, north to Utah and Wyoming, and east through Iowa, Indiana, Wisconsin, Minnesota, New York, southern Ontario, Saskatchewan, and Manitoba (Fernald 1950, Kearney and Peebles 1951). Little (1979) said the American plum grows in the mountains of northern Mexico, but that appears to be a confusion with *P. mexicana* (Standley 1920–1926).

Fruits of *P. americana* were used as food by at least the Apache, Cherokee, Cheyenne, Creeks, Crow, Dakota, Iroquois, Isleta, Kiowa, Meskwaki, Ojibwa, Omaha, Osage, Pawnee, Ponca, and Winnebago (Gilmore 1919, Hunter [1823] 1973, Densmore 1928, Yanovsky 1936, Sturtevant 1955, Moerman 1998). Bundles of the flexible twigs were used as brooms throughout the Missouri River region, and the Omaha planted their beans, corn, and squash when *kande* came into bloom (Gilmore 1919). Isleta, Navajo, and Ojibwa made dyes from the bark, producing yellow or red, depending on the other plants mixed and mordants (Moerman 1998).

Several tribes used *P. americana* in medicine (Moerman 1998). The Cherokee made a cough syrup of the bark, and an infusion for kidney and bladder problems (Hamel and Chiltoskey 1975). The Cheyenne applied the mashed fruits to mouth diseases, and the Meskwaki used the root bark. The Mohegan made an infusion of twigs to treat asthma. The Omaha boiled root bark and applied it to skin abrasions (Gilmore 1919). The Ojibwa made a decoction of the roots for intestinal worms and put a decoction of the bark on cuts and wounds as a disinfectant (Densmore 1928); they also used the rootlets in a remedy for diarrhea. The Rappahannock used the red plum in an undisclosed medicine.

The last southeastern plum to be named was *P. geniculata*. Roland M. Harper (1878–1966) described that species from Lake County in 1911, and it is so rare that it has been considered federally endangered since 1987 (Ward 1979, Coile 2000, Chafin 2001). Little (1979) did not even discuss the name. This small plum has fruits to about 2 cm wide and grows in the heart of what was Timucua territory before the arrival of the Europeans.

Moerman (1998) does not list *P. myrtifolia* as used by native people, and with its limited distribution in Miami-Dade County, that is not surprising. Like other species in the genus, this one contains hydrocyanic glycosides. Bark, leaves, and twigs are used fresh for asthma and cough in Cuba (Roig 1945). In Hispaniola and Puerto Rico the trunks are used for electric line posts, in rural construction, and in cabinetwork (Liogier 1974, Little et al. 1974). The bark has a strong smell of almonds and is used to clean false teeth (Liogier 1974).

Stephen Elliott named *P. umbellata*, called the “sloe of the South” because of its black fruits. At the time he named the plum, Elliott (1821) recorded that people were using the fruits in preserves. When they are available, they are preferred because they are unusually rich in pectin (Harrar and Harrar 1946). I found no records that they were used as a substitute for the European sloe (*P. spinosá*), but it would be a safe bet that they were.

The laurel-cherry (*P. caroliniana*) has the second most restricted range of the species, growing on the coastal plain from southeastern North Carolina to central Florida, west to eastern Texas (Little 1979; Diggs et al. 1999). Alabama people boiled the inner bark to make a red dye used to color split cane woven into baskets. Porcher (1863) was enthusiastic about these plants during the Civil War but largely as an ornamental. He wrote: “This tree, the flowers of which are much frequented by bees, grows abundantly on the sea-coast of our states, and is certainly one of the most beautiful and manageable evergreens that we possess. It can be cut into any shape, and is of a most attractive green

color. It forms an impervious hedge, and grows rapidly.” About its potential as medicine, Porcher continued: “The black, oval berries contain an abundance of Prussic acid, as does the whole tree; but I do not know of any use to which it is applied. Dr. Thompson has found great use from Prussic acid, largely diluted, as a local application in impetigo.” Hocking (1997) added that the leaves and bark contain prunellin, which hydrolyzes to racemic mandelonitrile and glucose and releases hydrogen cyanide. As with all members of the genus, laurelcherry may be fatal to stock if browsed in quantity (Harrar and Harrar 1946).

Wild black-cherry (*P. serotina*) grows from Florida to Texas and southern Arizona, south through Mexico (Baja California Sur, Sonora east to Tamaulipas, south to Oaxaca and Chiapas), Guatemala, and north to North Dakota and Minnesota, Nova Scotia, New Brunswick, southern Quebec, and southern Ontario (Fernald 1950, Little 1979). The Mexican and tropical American plants are usually segregated into *P. serotina* ssp. *capuli* (Felger et al. 2001), formerly recognized as a distinct species. Fruits from this subspecies have long been made into alcoholic and non-alcoholic drinks, and they are eaten fresh and preserved throughout the Americas (Felger et al. 2001).

The cherry now called ssp. *capuli* was first noted in Mexico by Hernando Cortez’s men in 1519 when the fruits were an important food for Spanish soldiers during the siege of Mexico City (Standley and Steyermark 1946). Francisco Ximénez said in 1615 that the fruits “*no son nada inferiores a nuestras cerezas*” (are not inferior to our cherries). Among the tribes in the United States, black-cherry fruits were used as food by the Cherokee, Iroquois, Menomini, Ojibwa, and Potawatomi (Smith 1933, Moerman 1998). Fernald et al. (1958) noted that indigenous people first pounded dried fruits (including pits) and then leached out the poisonous chemicals before using them in foods. An alternate view is that, once pounded, the poisons volatilize and fruits are rendered harmless (Dunmire and Tierney 1997).

The Cherokee also used the wood for buildings, furniture, and carvings (Hamel and Chiltoskey 1975). Trees now are highly prized for the beautiful wood, which is used for furniture and cabinetmaking (Vines 1977, Diggs et al. 1999). Porcher (1863) was similarly complimentary, writing, “The wood of this tree is highly valuable, being compact, fine grained, and brilliant, and not liable to warp when perfectly seasoned. When chosen near the ramifications of the trunk, it rivals mahogany in the beauty of its curls.” Others since have used the wood for furniture, cabinets, printer’s blocks, veneer, patterns, panels, interior trim, handles, woodenware, toys, and scientific instruments (Vines 1977).

Ximénez recorded that the Mexicans made a decoction of the bark that was used to cure “*las cámaras de sangre*” (blood clots). Also, the powder of the bark was used to clarify the vision, heal inflammations, moisten the tongue when it is dry from the heat or fever, and was used to cure various external sores and lesions (Martínez 1969). Ximénez considered the bark useful against malaria, but later reports considered it simply antipyretic (Martínez 1969). Tarahumara used the leaves and bark to catch fish and in a tea to treat whooping cough (Pennington 1958). They also added young leaves to their corn dish *esquite* to increase spiciness.

In the United States, the black-cherry is used as medicine by tribes throughout its range. Eastern tribes using it included the Catawba, Cherokee, Delaware, Illinois-Miami, Iroquois, Malecite, Micmac, Mohegan, Narragansett, Ojibwa, Osage, Penobscot,

Potawatomi, Rappahannock, Shawnee, and Shinnecock (Smith 1933, Vogel 1970, Moerman 1998). People typically used the bark in tea or syrup for coughs, fever, cold, sore throats, diarrhea, lung ailments, bronchitis, pneumonia, and dyspepsia (Foster and Duke 1990, Moerman 1998, Duke et al. 2002). In addition to those uses, Vogel (1970) recorded the Cherokee using a bark decoction to treat measles, and the Missouri River tribes treating dropsy with it (Gilmore 1919). The Catawba mixed black-cherry bark with poplar and dogwood to treat expectant mothers (Vogel 1970). Like several other eastern tribes, the Illinois-Miami put root bark on infected gums (Vogel 1970). The Osage and Shawnee mixed black-cherry bark with *Arisaema* and snakewort to treat malaria (Vogel 1970).

Among the non-indigenous people, Porcher (1863) gave a typical view when he wrote, "This is undoubtedly one of the most valuable of our indigenous plants." He listed many maladies for which blackcherry had been used successfully, but like indigenous tribes considered it best against diarrhea, colds, and coughs. One of his favorite recipes was for "making 'Cherry' cordial by the Southern matrons in the lower country of South Carolina (Saint John's)—a most delectable drink at all times, but particularly valuable in the present emergency [Civil War]: Fill the vessel with cherries (not washed, if gathered clean). Cover with whisky. After several weeks pour off all the clear liquor and press the cherries through a sieve. Put into the juice thus pressed out five pints of brown sugar, and boil with syrup enough to sweeten the whole demijohn. Pour five pints of water on the thick part; boil and strain to make the syrup with the sugar." Murphee (1965) found residents of the Panhandle still using the gum to make a remedy to relieve colds and croup. The fruits are still a flavoring for rum and brandy (Uphof 1968, Diggs et al. 1999).

We partly owe the success of the Lewis and Clark expedition to choke-cherry bark (De Voto 1981). There were several occasions when the leaders were required to give remedies to individuals during the journey, and Captain Meriwether Lewis's mother had been a skilled herbalist or "yarb doctor" (Vogel 1970). On 11 June 1805, between Maria's River and the Great Falls on the Missouri River in Montana, Lewis became ill with abdominal cramps and fever. He had no medicine with him at the time so he decided to use choke-cherry. He brewed a strong decoction of small twigs and leaves and drank a pint at sunset. An hour later, he drank another pint. By 10 P.M., his cramps and fever were gone.

Lewis had used the other choke-cherry (*P. virginiana*), but his technique was based on what he learned for using the eastern *P. serotina*.

### *Pseudophoenix*

(Charles Sprague Sargent adapted H.A.Wendlan's name *pseudo*, false, *phoenix*, genus of the date palm)

*Pseudophoenix sargentii* a. Habit, b. Section of leaf midrib showing attachment of segments, c. Branchlet of inflorescence, d. Complete staminate flower and longitudinally dissected staminate flower, e. Floral diagram of staminate flower, f. Complete perfect flower and longitudinally dissected perfect flower, g. Floral diagram of perfect flower, h. Fruits. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*Pseudophoenix sargentii* (named for Charles Sprague Sargent, 1841–1927, director of the Arnold Arboretum of Harvard University)  
buccaneer palm (Bahamas)

*cathier* (wine tree, Haiti); *chacha* [*cacheo*, *caicha*, *casei*, *catey*] (wine, Dominican Republic); *palma de cacheo* (wine palm, Dominican Republic) [Florida, Sargent's] cherry palm (Florida, Puerto Rico)  
hog cabbage-palm [*palmetto*] (Bahamas)

*palma de Guinea* (palm from Guinea, in the belief that the tree was from Africa, Cuba)

*palme marron* (wild palm, Haiti); *palmiste [à vin, mâle]* ([wine, male] palm, Haiti)

These palms were not even discovered until the late 1800s. Four species are known in the genus, all endemic to the Caribbean (Mabberley 1997).

In Hispaniola, people extract from the trunk a sweet liquid, which ferments into a drink called *cacheo* (Liogier 1974). In Dominica, Puerto Rico (Mona Island only), and Florida these trees are nearing extinction, perhaps due to overuse by humans (Coile 2000, James 2003). At one point the Hispaniolan *P. eckmanii* was thought to have been extinct since 1926 due to overharvesting for winemaking, but it has been relocated (Zona 2002).

### ***Psychotria*: Wild Coffee**

(Based on Greek *psyche*, soul or life, plus *iatria*, medicine, or “to give life”)

***Psychotria nervosa*. Drawn by  
P.N.Honychurch.**

Imagine a world without coffee (*Coffea arabica*). There was no coffee in the Americas before the plant was introduced. Perhaps more surprising, there was no coffee in Europe when Columbus sailed in 1492.

German physician Leonard Rauwolf (1535–1596) was the first European to mention coffee after his trip to the Levant in 1573–1576. Still, it was 99 years after the New World was discovered before much attention was paid to the beverage by Prosper Alpinus in 1591. About 200 years after Europeans settled in the New World, the French introduced *Coffea arabica* into Martinique in 1717, and the Dutch took it to Suriname shortly before that. The plants reached Jamaica in 1728 (Hedrick 1919).

Before the comparison between cultivated coffee and wild plants could be made, *Coffea* had to be introduced into the New World. “Wild coffee” was first applied to its relative *Faramea occidentalis* by Philip Miller in 1730. That plant is also a member of the Rubiaceae, the family containing *Coffea*, along with what is now called wild coffee in Florida (*Psychotria nervosa*, *R. sulzneri*). When the name “wild coffee” was extended from *Faramea* to *Psychotria* is unknown. However, both genera are still known by that common name in English, French (*café marron*, Guadeloupe, Martinique), and Spanish

in the Caribbean (*café cimarrón*, wild coffee, Dominican Republic), and Mexico (*kapee ts'ohool*, coffee herb, Huastec, San Luis Potosí). There is an indirect reference to the place of coffee origin in Africa with *palo moro* (Moorish tree, Puerto Rico).

Although *Psychotria* is compared with coffee, it is not used as a beverage. Several people have told me they tried using *Psychotria* seeds as a substitute "coffee," and got only bad taste and terrible headaches from the mixture. However, these plants are surely rich in tannins because mashed leaves are used as a hemostat in Cuba (Roig 1945) and Puerto Rico (Melendez 1989). People in Barbados use a leaf decoction as a febrifuge, as a remedy for colds, and to treat stomach ailments. Leaves are combined with other plants as "bush tea" (Goodding 1940–1942), which is used to treat a number of maladies. In keeping with their multiple common names, the Huastecs of Mexico have the most varied uses (Alcorn 1984). Like Barbadians, the Huastecs use it to treat respiratory problems, especially asthma. Other uses include application to local swellings, such as swollen feet, and erysipelas, sores, boils, tumors, and skin fungus. Does *bois laitelle* (milk trees, Haiti) mean they use it with milk?

Before *Coffea* was introduced into the New World, people here used other names for the *Psychotria*. The only indigenous name from within Florida is for *P. sulzneri*. This hammock shrub is known by the Seminoles as *atópá:bí* (dogwood replica, Mikasuki). According to Sturtevant's (1955) informants, the plant was "useless." However, that name was derived from Creek *vtvphv* [*atápha*] for dogwood (*Cornus*), and that comparison with another species suggests a loss of information (see *Cornus*). Every species of *Cornus* in North America was used by people of essentially every culture (Moerman 1998).

Florida's other "wild coffee" (Florida, Bahamas, Puerto Rico), *P. nervosa*, has a diversity of names outside the state. Among those names is *ipecacuana ondulada mayor* (big ipecacuanha with undulate leaves) in Cuba (Roig 1945). That name was given because the roots of *P. nervosa* were used as an emetic as were those in the real *ipecacuanha* (*P. ipecacuanha*). The comparison is instructive, because *ipecacuanha* has a long history.

Between 1570 and 1600, the Portuguese priest Manoel Tristão was in Brazil where he learned that the Tupi people used the roots of a plant for treating dysentery. When he returned to Europe, he told more people about the plant, and French physicians finally made it available in 1672 (Burkill 1966). We get our English name *ipecacuanha* from the Tupi-speakers in South America who called their medicinal plant *ipega'kwai* (duck's penis) or *ipe-kaa-guéne* (creeping plant causing vomiting). The Florida plants have no such imaginative names.

The only name other than "wild coffee" found in Florida is Seminole *balsamo*, given by Morton (1981). Since she gives no source for the name and it has not been found elsewhere, the origin remains a mystery. There is documentation for the name *bálsamo* in Puerto Rico (Liogier and Martorell 1982, Meléndez 1989). Literally translated, the word means "balsam." The probable sense of its use for "Seminole *balsamo*" is the now archaic meaning of "soothing." Etymologically, the word in Spanish and English has been equivalent to "balm," both having been derived from Latin *balsamum*. The very name itself suggests a long medical history—unless Morton invented the name.

Some of the other designations indicating use as a medicine are kidney bush (Caymans) and St. John's bush (Barbados). While perhaps not exactly "medical," the

name strong back (Caymans) suggests enhanced stamina. Since the name implies two distinct applications of strength, it was perhaps an important plant. The interpretation most often given for such names is improved sexual stamina. However, there was an equally valuable application. Since our species became bipedal, we have suffered from innumerable back problems. In addition, as the name is endemic to the Virgin Islands where the population is largely derived from slaves, it takes on added meaning. Individuals who could not do their share of work during slaving times were not likely to survive long. Medicines to “soothe” aching backs would have been at a premium.

Other names show different perspectives. The names *penda* (dangler, Dominican Republic) and *tapa camino* (path coverer, Cuba) are surely related to the locations where these shrubs grow and are descriptive of their life-forms. *Plateado* (folded or plaited, Cuba) is a literal equivalent of the specific name of the technical synonym *Psychotria undata*. That name was proposed by Nicolaus von Jacquin in his book of 1798, *Plantarum Rariorum Horti Caesarei Schoenbrunnensis*, and he too was taken with the undulating pattern of the living leaves. For some reason not understood, the plant is called *huesito* [*husito*] (little bone) in Panama. If that were an isolated case, it would be one thing, but that word is applied to several Mexican species. None of the uses suggests a bone medicine, so perhaps the name refers to the wood.

Mayans call this shrub *ya'ax-k'anan* [*anal anal xiv, sacxanal, canaan*] (*ya'ax*, green, *k'anan*, necessary, Yucatán), which is their same designation for *Hamelia patens*. Both plants are important in Mayan religious ceremonies, and other people also have names with reverent implications. Although the plants are not mentioned in the recent book on Haitian voodoo (Beauvoir et al. 2001), the names *cabra blanca* (white goat, Dominican Republic) and *cabra santa* (holy goat, Dominican Republic) suggest involvement with that religion. It is locally well known that the Santarias, a Cuban religious group related to voodoo (Voeks 1997), leave both goat and chicken offerings to their deities on the steps of the Miami-Dade County courthouse. So, *cabra santa* carries special meaning, and a *cabra blanca* is the best offering.

The most information available about the religious and medical importance of *P. nervosa* is among the Huastec (Alcorn 1984). There the shrub is *wats'ul*, a simple name denoting great age. *Wats'ul* also has a number of alternate names, including *tsakam wats'ul* (little *wats'ul*, Veracruz) and *wach'ul ch'ohool* (*wach'ul* herb, Veracruz), perhaps denoting a taxonomy that does not match ours. The names *baina ts'ohool* (sheath herb, San Luis Potosí), *itsalkw'a'* (toad chile, San Luis Potosí), and *tse'tsem ts'ohool* (woodpecker herb, San Luis Potosí) may also imply religious significance. The name *tsabalte' ts'ohool* (skin fungus herb, San Luis Potosí) points to a medicinal use, and the names *tse'tsem t'abat'* (little *Tabernaemontana alba*, San Luis Potosí), and *tsakam tsabalte'* (little *Cestrum dumetorum*, San Luis Potosí) compare it with other plants important among those people. People in Belize say it is *contra yierba* (herb against), which is the description often given to a strong plant used to counteract poisons, or at least some problem from an outside source.

The genus *Psychotria* was named by Linnaeus because of the reputed medical properties of some species. Which species he knew about being medicinal is more of a problem, as there are perhaps 1650 in the genus (Hamilton 1989a,b,c, Nepokroeff et al. 1999). However, discoveries in the late 1960s led to a renewed interest in *Psychotria*. Studies among people in the Amazon revealed that one or more members of the genus

were added to the psychoactive plant mixture called *ayahuasca* (vine of the soul, Quechua), used for religious, medicinal, and social purposes (Pinkley 1969, Schultes and Raffauf 1992). Subsequently, several studies of the genus have revealed alkaloids, benzoquinones, cyclic peptides, and other chemicals that exert a variety of influences on human physiology (e.g., Beretz et al. 1985, Adjibade et al. 1991, Amador et al. 2000, 2001, Khan et al. 2001, Verotta et al. 2002). None of the studies examined the Florida species, and the large genus is considered paraphyletic (Nepokroeff et al. 1999). Inferences of what might be the potential chemical bases for uses of *P. nervosa* or *P. sulzneri* are impossible, particularly because not all species contain the same classes of active compounds (Leal and Elisabetsky 1996).

Still, the Huastec of Mexico use *wats'ul* as a love charm, and that is as good as any. You simply grind the seeds and carry them in a pocket. What could be easier?

### *Ptelea*

(From *ptao*, to fly, the Greek name for the elm, reapplied by Linnaeus to this genus with a similar fruit; akin to Akkadian *petelu*, to wind, entwine)

*Ptelea trifoliata*. From Sargent 1905.

#### *Ptelea trifoliata* (three-leaved)

ague bark (from the use to treat malaria)

*cola de zorillo* (little skunk tail, Texas, Arizona, Sonora, Chihuahua, Tamaulipas, Veracruz); *vara de zorro* (fox bush, northern Mexico to Veracruz); *zorillo* (little skunk, Hidalgo; because plant and animals have a similar odor)

*dreiblättrige Lederbaum* (three-leaf leather-tree, German, fide Millspaugh 1893); *Lederstrauch* (leather bush, German)

[common, three-leaf, woolly] hop-tree [hoptree] ("hop-tree" dates from ca. 1877, with the substitution of the fruits of *Ptelea* for those of hops, *Humulus lupulus* for making malt liquor, and as a tonic and soporific)

*orme de samaire à trois feuilles* (samara elm with three leaves, French; fide Millspaugh 1892)

pickaway[-anise]

*pinacatillo* (comparing the smell with the pinacate beetle, Coahuila; from Nahuatl *pinacatl*, their name for the beetle *Elodes* spp.,

Tenebrionidae, a black insect that sprays an irritating, stinking chemical for defense)

potato chip tree [potatochip-tree] (alluding to the flat fruits)

prairie grub

*psehtin* (Lakota)

quinine-tree (a name comparing these shrubs with *Cinchona* spp., the source of the anti-malarial compound quinine, an alkaloid first isolated in 1820 by French Pierre-Joseph Pelletier and Joseph-Bienaimé Caventou; the word “quinine” appeared in English by 1826, although it had been used in Spanish as *quina* or *quinaquina*, taken from Quechua, since at least the 1640s)

*sinaptahaspi* (*sinapó*, ash, *tahaspi*, light [weight], Koasati)

skunk-bush [skunkbush] (the odor caused comparison with the skunk, whose name was taken from the indigenous Abenaki *seganku* or *segongw*, the weasel relative *Mephitis mephitis*)

stinking-ash; wafer ash (“wafer” refers to the flat, rounded fruits, like the thin, crispy cake that gave rise to the Old English *wafre*, and our word “waffle”; the word “ash” compares it with *Fraxinus* because of the leaves)

swamp dogwood (a misnomer or misidentification; this is an upland plant)

[shrubby, tree] trefoil (called “trefoil” from Latin *trifolio*, three leaves because of the compound, trifoliate leaves)

wahoo (from *uhawhu*, a Creek word for the elm; however, the Dakota *wahú*, arrowwood, was applied to *Euonymus*)

wing-seed

The first living hop-trees to arrive in Europe were those sent to England by Reverend John Banister in 1704 (Millspaugh 1893). Those plants died, but Mark Catesby reintroduced the shrubs about 1724. Subsequently, hop-tree was cultivated in other places in Europe.

Both Leonard Plukenet in 1696 and Johann Jakob Dillenius in 1732 had studied specimens of these plants and called them *Frutex virginianus trifolius*, *ulmi samaris* (three-leaflet shrub from Virginia, with samara fruits like the elm). When Linnaeus examined the shrubs, he realized they were distinct from the elm, which he called *Ulmus* (which see). Linnaeus began calling the New World plants *Ptelea* in his *Hortus Cliffortianus* of 1738 and continued using the name in *Species Plantarum* ([1753] 1957).

Although Linnaeus knew *Ptelea* only from Virginia, William Bartram ([1791] 1958) recorded the shrubs in North and South Carolina, Alabama, Georgia, and northern Florida between 1773 and 1777. André Michaux, during his visit to Florida in 1788, found the plants in Alachua, Levy, Orange, and Putnam Counties (Taylor and Norman 2002). There are now about 11 species recognized in this North American endemic genus (Bailey 1962, Mabberley 1997). Numerous varieties of *P. trifoliata* have been named, and these intergrade in a confusing manner.

Perhaps the first record of medicinal use of the wafer-ash in the Americas was by the German physician Johann David Schoepf (1752–1800) who visited during the Revolutionary War in 1783–1784. He and others of the period considered it aromatic,

bitter, stimulant, and an expectorant tonic useful against malaria (Millspaugh 1893). They surely learned about the plant directly or indirectly from indigenous people, but that does not seem to have been recorded.

Later, Rafinesque reported *Ptelea* in his *Medical Botany* of 1830. As usual, he obtained much of his information from indigenous people, but typically declined recording who and where. Rafinesque considered the plants vulnerary and vermifuge (Millspaugh 1893). Based on his report, the plants were most likely used by tribes where he explored; however, actual reports have been found for only two groups not visited by Rafinesque. The Menominis considered the root bark of *P. trifoliata*, a plant brought to Wisconsin from Kansas, as a sacred medicine and panacea to season and render other medicines potent (Vogel 1970). The Meskwakis used it similarly, and for lung problems, often in tea with other barks (Vogel 1970). Those reports are also the only ones found by Lewis and Elvin-Lewis (1977) and Moerman (1998) regarding indigenous people in the United States. However, in Mexico the plants are still used in remedies for dyspepsia, as a mild tonic, in a bath of an alcoholic infusion of leaves against chills, and to treat rheumatism (Martínez 1969).

Following Rafinesque, several American physicians promoted wafer-ash as a medicine. Eclectic physicians considered it second only to *hydrastis* (*Hydrastis canadensis*) as a tonic, and they thought a cold infusion of the plants especially good for debilitating fevers (Culbreth 1910, Felter 1922).

Martínez (1969) reported that the bark of the root contains the alkaloid berberine, but that has not been confirmed in more recent chemical studies. It does contain a variety of alkaloids, including dictamnine, pteleine, ptelecultiunum, pteleatinium chloride, and several others. In addition to the alkaloids, the plants produce coumarins (Bailey et al. 1971, Szendrei et al. 1973, Mitscher et al. 1975a,b, Petit-Paly et al. 1987, 1989). At least the pteleatinium chloride is antibacterial, and some of the other compounds are antipyretic, antifungal (antiyeast), and effective against the tuberculum bacillus (Hocking 1997, Mabberley 1997). Decoctions from roots have been used as a stomach tonic and for oral and throat diseases (inflamed uvula). The leaves and shoots still are considered anthelmintic (Hocking 1997, Vasquez and Jacome 1997). Equal parts of fresh leaves and bark are used by German homeopaths (Hocking 1997). According to Diggs et al. (1999) the plants contain a poisonous saponin that causes photodermatitis.

Fruits have been substituted for hops in making beer since at least 1868 when Asa Gray recorded that use (Hedrick 1919, Vines 1977).

### *Pteridium*

(J.A. Scopoli, an Austrian physician and professor of natural history in Pavia, named the fern with Greek *pteridion*, small fern, a diminutive of *pterus*)

*Pteridium aquilinum*. Drawn by  
P.N.Honychurch.

***Pteridium aquilinum*** (of an eagle, from the wingshaped fronds or leaves)  
*achshikimiinshi* [*achsh'kiwmiinshi*] (*ach*, abundant, *sh'kiw*, urinate,  
*miinshi*, tree, Delaware)

*Adlerfarn* (eagle fern, German); *eagle fern*; *fougère d'aigle* [*fougère de*  
*aigles*] (eagle fern, Quebec); *helecho de aguilo* (eagle fern, Colombia)

[southern] bracken (perhaps from Scandinavia, akin to Old Swedish  
*braekne*, fern, USA, Bahamas)

[hog, pasture]-brake (from Old German, *brache*, “wasted” [i.e., wild]  
land)

*fatí:yá:bí* [*faitiyabi*] (turkey leg replica, Mikasuki); *pinilio:má*  
(*penwv*, turkey, *ele*, leg, *ome*, resembling, Creek); *fi:tiyyí* (*fi:tó*, turkey,  
*iyyí*, foot, Koasati); *tapitapí* (an archaic name, Koasati)

fiddleheads [fiddleheads] (the young fronds resemble the head of a  
violin, in use by 1599)

*fourchette* (table fork or breast bone, Haiti)

*grande fougère* (big fern, Quebec); *helecho* (fern, Panama, Belize)

poor man's soap (Alabama)

*raineach-mhór* [*rainich móire*] (Mary's fern, Gaelic)

Although Moerman (1998) and Balick et al. (2000) separate *Pteridium aquilinum* var. *caudatum* into *Pteridium caudatum*, Wunderlin (1998) retains both as a single species. Regardless, *P. aquilinum* is widespread and was used by people from Alaska to Mexico and Florida. Among the relatives of Florida people, the Koasati made a decoction of the roots for chest pain (Taylor 1940). The Seminoles used the plant for “Turkey Sickness” (permanently bent toes and fingers) (Sturtevant 1955). Murphee (1965) found people in the Panhandle making a tea from the plants to treat burns.

Farther north, the steamed mature fronds are used to make medicinal teas and inhalants for lung disorders and headaches (Moerman 1998). The young buds (fiddleheads) are edible. Older parts are poisonous (Morton 1968b), and King (1984) warns against using it for food at any stage. Yellow and green dyes are extracted from the roots (King 1984, Tull 1999).

### ***Pterocaulon*: Blackroot**

(From Greek *pteron*, wing, plus *kaulos*, stem)

Within the United States, there are relatively few plants whose roots yield a black sap. The two in the southeast are called “blackroot.” Scientifically, the herbs belong to the genus *Pterocaulon*. The green leaves with their white undersides merging into the stem and extending downward toward the ground, like wings, are as characteristic as their black roots. The first information Europeans had of these plants was when Linnaeus called them *Gnaphalium virgatum* in 1759. However, it was Stephen Elliott, an American professor in Charleston, South Carolina, who gave them the Greek name fitting their morphology in 1823.

For many years, it was believed that a single species grew in the United States, and it was called *P. virgatum*. Then, when the Frenchman André Michaux, who explored the Carolinas and Florida,

***Pterocaulon pycnostachyum.*** Drawn  
by P.N.Honychurch.

looked more closely, he realized that there were two different species. One species grew in the southeastern states (North Carolina to Florida, west to Mississippi), and the other in Texas, eastern Mexico, and the West Indies. The species name *virgatum* had already been applied to the western species, so Michaux called the one in the southeast *Conyza pycnostachya* (*pycno*, thick, *stachyo*, spike, in reference to the flower cluster). Then, in 1823, Stephen Elliott moved the species to *Pterocaulon* to create the name used now, *Pterocaulon pycnostachyum*. Later, in 1836, Augustin-Pyramus de Candolle moved *virgatum* to create the name *Pterocaulon virgatum* for the western species.

Both species have long been called blackroot or Indian blackroot in the United States, but they sometimes also are called rabbit tobacco. The last name is more often applied to members of *Gnaphalium*, the genus where Linnaeus originally put these plants. Our word tobacco came into English from Spanish *tabaco*, first used in the 1500s but taken from a Taino word in Hispaniola. The modifier “rabbit” is equivalent to saying “wild” to distinguish it from the cultivated *Nicotiana*. Comparison with *Nicotiana* results from *Pterocaulon* leaves being smoked or chewed either as a medicine or simply because tobacco was not available.

The western species, *P. virgatum*, has a richer history of common names than the eastern plants, surely because that species is geographically spread from Texas to Argentina, and in the Caribbean. It too is called blackroot or Indian tobacco in the United States. However, Jamaicans call it golden cudweed. That Jamaican name is based on the Old English *cwidu* or *cudu*, which is sometimes also rendered *quid*. Those words date

from about A.D. 1000 and refer to any plant substance that is held in the mouth and masticated, but not swallowed. Typically, after the introduction of *Nicotiana* into the Old World, the “cud” has been synonymous with that species. However, the practice of chewing a cud is much older in Europe than knowledge of the American *Nicotiana*.

Other people were more impressed with the looks of the aboveground parts of these plants. Due to the white pubescence, people call them *branqueja* (the white one, Brazil), *calça de velho* (old man’s shoes, Brazil), or *oreille mouton* (sheep’s ear, Martinique, Dominique). *Pterocaulon* is called *langue à vache femelle* (female cow’s tongue, Martinique, Dominique) to distinguish it from *langue a vache*, which is *Elephantopus*. Because the plants retain their shape and color when dried, they are also called *siempreviva* (everlasting, Cuba). References to where one may find the plants are in some names—*alecrim das paredes* (rosemary of the walls, Brazil), *travesera de loma* (crosser of hills, Cuba), and *vela de sabana* (savanna candle, Dominican Republic). Allusions to the potent chemicals contained in the herbs are *barbasco* [*verbasco*] (a fish poison, Brazil) and *cur a nacio* (cures at birth, Dominican Republic).

The eastern *P. pycnostachyum* has names only in English and in two Seminole languages. Sturtevant (1955) found literature with various spellings of these names back to the 1930s, and then wrote that Mikasuki *picikcalah kayikci* meant “blood saver medicine.” That is the same sense *aspehekche alahke aayek* that the modern Mikasuki speakers translate more exactly (*pehekche*, blood, *alahké*, leftover, *ayekche*, medicine). “Blood medicine” is the Mikasuki name *pehekche emayekche* recorded by Snow and Stans (2001).

Williams ([1837] 1962) may have been the first person to record that this plant was used by the Seminoles. He wrote that it was “[t]he famous Indian remedy for pulmonary disorders.” Sturtevant (1955) later recorded that the Seminoles used these plants widely in medicines where there was a real or perceived problem with the blood. The plant was used to treat chronic sickness, coughs and colds, “Cow Creek Sickness,” fever, menstrual difficulties, “Otter Sickness,” and was used in childbirth. Modern Seminoles who recall the old medicines still note similar uses (Snow and Stans 2001).

Chemical studies of several *Pterocaulon* species show that the plants contain a variety of coumarins (Debenedetti et al. 1981, 1991, 1992, 1994, 1996, 1997, 1998, 1999, Magalhaes et al. 1981, 1989, Boeykens et al. 1994, Vilegas et al. 1995, MacLeod and Rasmussen 1999, Palacios 1999, Vera et al. 2001). Coumarins have a long history of use as a blood anticoagulant (Lewis and Elvin-Lewis 1977). Coumarins are lactones, which are vitamin K antagonists, and they act as indirect anticoagulants with a delayed effect. Following oral ingestion, absorption, and metabolism in the liver, chemical action results from a reduction in synthesis of prothrombin, a plasma protein produced in the liver in the presence of vitamin K. Prothrombin is converted into thrombin during the clotting of blood. Alterations of these pathways change the ability of blood to clot, and noticing this change is surely partly what led people to use these plants. Clotting alteration would have been the obvious result when people used *Pterocaulon* as abortives and styptics, and to relieve menstrual difficulties (Sturtevant 1955, Uphof 1968, Morton 1974).

Coumarins and their derivatives are not the only bioactive chemicals in *Pterocaulon*. Other studies show that the plants contain caffeolyquinic acids (Martino et al. 1979), thiophene acetylenes and flavonols (Bohlmann et al. 1981), flavonoids (Semple et al. 1998, 1999), flavanones, and caryophyllene (MacLeod and Rasmussen 1999). These

chemicals are antioxidant, prooxidant (Desmarchelier et al. 1997), and antiviral (Semple et al. 1998, 1999). Thus, the mixture of chemicals extracted into medicines made from *Pterocaulon* would be effective against colds and asthma.

Sturtevant (1955) also recorded the Creek name for these plants, and Snow and Stans (2001) confirm that it is still used. In Creek, the plants are *yvnvsv heleswv* [*yanasa hiliswâ*] (*yvnvsv*, buffalo, *heleswv*, medicine). The allusion to a buffalo may seem odd in the modern world largely devoid of them. However, *Bison bison* historically ranged into the woodlands of the eastern United States well within the area occupied by the Creeks and ancestors of the Miccosukees (cf. Caras 1967).

The Seminoles also sometimes used blackroot in the busk (Capron 1953), a term derived from their word *posketv* [*poskita*] (to fast, Creek). The busk, or Green Corn Ceremony, involves a 4-day festival, sometimes with 1 to 3 preliminary days added. The event occurs between late April and mid-July. Special busk grounds are prepared distant from both Seminole and white settlements. During the evening of the third day, fires are rekindled with flint and steel in the old manner, and the sacred medicine bundle is opened. The contents of the medicine bundle are usually kept secret, but at least three outsiders in recent history have been permitted to examine it. Spoehr (1939), Capron (1953), and Sturtevant (1954) were each permitted to make notes on the contents of different medicine bundles. Each of the three found similarities and differences in the contents. Capron (1953) is the only one who found *Pterocaulon* in the bundle. Regardless of the exact contents of the medicine bundle, a variety of its plant contents (up to 20 plants) was used to brew the *ayikctanahki* (gathered medicine) or *ayikctanahkco:bi* (big gathered medicine), a critical beverage in the cleansing of the old year and preparation for the new.

The only other record of use of *Pterocaulon* found from Florida was by Murphee (1965). She was told that people in the Panhandle used it to cure “teen age trouble” (illegitimate pregnancy).

The genus contains 18 species in the warm parts of the Americas and southeastern Asia, reaching to Australia and New Caledonia (Cabrera and Ragonese 1978). Within its range, medicines are known to be made from it in the United States, Argentina (Vera et al. 2001), Brazil (Magalhaes et al. 1989), and Australia (Cribb and Cribb 1981, Semple et al. 1998, MacLeod and Rasmussen 1999). Perhaps not surprisingly, the aborigines of Australia also use the leaves as a tobacco substitute (Cribb and Cribb 1981). Nothing has been found to corroborate the inference, but maybe that is why Uphof (1968) said blackroot was a “stimulant” and Morton (1974) simply wrote that it was “narcotic.” Nothing about its chemistry suggests those impacts on users.

Possibly the leaves are poor substitutes for *Nicotiana*. That might be why it was called “rabbit” tobacco. Either way, the common name conjures up the image of some pensive rabbit sitting on its haunches puffing on a pipe.

### *Pycnanthemum*

(André Michaux created this name with Greek *pycnos*, dense, and *anthemon*, a flower, from the compact inflorescences)

[American wild] basil (comparing the fragrance to the cultivated basil, *Ocimum basilicum*)

*Dickblume* (dense flowers, German)

mountain-mint (William Salmon included “mountain-mint” in 1671 in his *Synopsis Medicina* for what is now *Clinopodium*, with about 20 European species; the name later was shifted to the New World, and “mountain-mint” used for *Pycnanthemum* by 1861)

***Pycnanthemum albescens*.** From Britton and Brown 1898.

***Pycnanthemum albescens*** (whitish)

*sak:fotó* [*iskafotó*] (Koasati; probably cognate with Creek *kyfockv* [*kafóckd*]; cf. *Piloblephis*)

*shinukititeli* [*shinuktelele*] (*shinuk*, sand [probably originally *shilup*, ghost], *titeli*, to drive out, Choctaw; this name is a variant of the one used for *Monarda punctata*, which see)

white [white-leaf] mountain-mint [whiteleaf mountainmint]

***Pycnanthemum flexuosum*** (curved alternately in opposite directions)

Appalachian mountain-mint [mountainmint]

dysentery weed

My education about *Pycnanthemum* began when I was working with my undergraduate professor Gordon Hunter. He had become interested in the mints and hired me in the 1960s to collect and work with him on some of the problems in the western Kentucky species. I knew the plants in the Jackson Purchase region of Kentucky between the Tennessee and Mississippi Rivers, but he had me look more closely at them. During the time that I was gathering specimens for him, I did not know that they had a long and complicated history of association with people.

An early mention of what is now *P. virginianum*, published in 1697 by Paulo Boccone (1633–1703/04), an Italian monk, physician, and professor at Padua, alludes to its medical application. He called the plants *Serpentaria virginianus* (Virginia snakeroot), and plants with that name were considered remedies for snakebite. That common name

has been applied to numerous plants in different genera over the past few centuries (cf. also *Aristolochia*).

In 1696, Leonard Plukenet discussed the same species, but he gave it the phrase name *Clinopodium, pulegii angusto rididoque foliio, virginianum* (*Clinopodium*, with narrow and rigid leaves like *pulegium* [pennyroyal], from Virginia). Both Jan Gronovius's *Flora Virginica* and Linnaeus's *Hortus Cliffortianus* followed Plukenet's lead in thinking the herbs were a *Clinopodium*, but another early student of the herbs thought differently. In his 1699 book, Robert Morrison emphasized that the Virginia plants should be a distinct species of *Pulegium*. After further study, Linnaeus changed his mind, and in 1753 he called the plants *Satureja virginiana*. Thus, in the first 57 years that single species had been known, it had been placed in four genera. People are still debating placement of many species in the Lamiaceae, as genera of mints remain problematical. However, most now agree that the species discussed from Plukenet to Linnaeus is *Pycnanthemum*, a genus created by Michaux in 1803. We now know of 17 species endemic to North America (Mabberley 1997).

Indigenous people in the eastern United States have long been familiar with *Pycnanthemum*. People from the Ojibwa of southern Canada to the Cherokee of the Carolinas are recorded as using the plants in seasoning food (Densmore 1928, Hamel and Chiltoskey 1975). As Fernald et al. (1958) noted, most of the aromatic mints have been used as food additives to improve flavors. The common name "basil" or "American wild basil" widely applied to *Pycnanthemum* alludes to a more widespread application in seasoning food than most literature suggests. It is known that *P. muticum* contains several volatile oils including pulegone, menthol, menthone, and limonene; presumably all species contain different mixtures of those aromatic compounds (Hocking 1997). Porcher (1862) was especially complimentary to the family when he wrote that it does "not contain a single unwholesome or even suspicious species; their tonic, cordial, and stomachic qualities are due...to the presence of an aromatic, volatile oil, and a bitter principle."

Medicine and food blend in most cultures so that it is not always possible to distinguish one from the other. However, several tribes considered different species of *Pycnanthemum* a good remedy for colds (Moerman 1998). Foster and Duke (1990) say that all species were used interchangeably.

In the southeastern United States, the Choctaw used a leaf decoction to promote sweating in treatment of colds (Bushnell 1909, Taylor 1940). The Koasati put the whole *P. albescens* plant in water, then used it to stop nosebleed. Roots mixed with those of *Salix nigra* were boiled, and the decoction drunk to relieve headache (Taylor 1940). To relieve contagion of death (*onalfapó*) leaves were put in cold water and the resulting mixture drunk and used to bathe the body while facing east (Kimball 1994). The Choctaw, the Koasati, and the Cherokee also used another species that does not grow in Florida, *P. incanum* (Hamel and Chiltoskey 1975, Taylor 1940). *Pycnanthemum incanum* was used similarly to the second Florida species, *P. flexuosum*. The Cherokee used Appalachian mountain-mint in a poultice to relieve headache, diarrhea, upset stomach, colds, and heart trouble, and to bathe inflammations, particularly those of the penis (Hamel and Chiltoskey 1975).

By the early 1860s, *Pycnanthemum* was used through much of the eastern United States, and it was also known in Europe. In 1861 the British botanists John Lindley and

Thomas Moore published their *The Treasury of Botany*. They gave *Pycnanthemum* the common name “mountain-mint,” a designation indicating medical use. As Lewis and Elvin-Lewis (1977) point out, *P. flexuosum* was famous during that time under the alternate name “dysentery weed,” and it was widely used throughout the southeastern states for bowel problems. Curiously, neither Porcher (1862) nor Millspaugh (1893) mentions *Pycnanthemum*, although they discuss a number of other mints, largely European, that were in use as medicines. Perhaps they thought that these wild plants had no virtues that warranted their substitution for plants already in people’s gardens.

### *Pyrhopappus*

(From Greek *pyrros*, fire or flame-colored, and *pappos*, fluff or downy appendage, an allusion to the pappus of the fruits)

#### *Pyrhopappus carolinianus* (of Carolina)

*boñ-yai* (Kiowa)

Carolina desert-chicory [Carolina desertchickory]

[false, native]-dandelion

sunflower (Louisiana)

*toñ-awdl- 'kok-yai* (Kiowa)

This genus of three species endemic to North America was named by de Candolle in 1838 (Kim and Turner 1990). Prior to that, Thomas Walter had named this species in his *Flora Caroliniana*, but he put it in another genus. All three species occur in Texas (Diggs et al. 1999), but only *P. carolinianus* ranges into the eastern states. In the east it grows from Texas to Florida, north to Delaware, southern Indiana, Missouri, and Kansas (Fernald 1950). The variation within the genus is complex because of apparent hybridization (Barber and Estes 1978, Petersen et al. 1990).

At least two—and perhaps all three—species were used by indigenous tribes. In the southeastern states, the Cherokee used an infusion of *P. carolinianus* to purify the blood (Hamel and Chiltoskey 1975). Farther west, in the southern Great Plains, the Kiowa ate the roots. They considered them good, but said they were much sweeter in the autumn (Vestal and Schultes 1939). In New Mexico and Arizona, the Navajo used the flower stalks of *P. pauciflorus* as an emetic, and the Keres knew the plant but professed no use of it (Moerman 1998).

Porcher (1863), Millspaugh (1892), Foster and Duke (1990), Bown (1995), and Duke et al. (2002) do not mention the plants.

# Q

## ***Quercus*: Oaks, Live and Otherwise**

(Classical Latin name of oaks)

Thomas Mann delighted in scavenging food. Tom was my friend and student in the early 1970s, but in another era, he would have been a “hunter-gatherer.” In the 20th century, he only gathered.

From time to time, I provided Tom with information on plant edibility in exchange for a sampling of his vegetable products. His acorn bread is particularly memorable. I think I remember it because it was chocolate brown; he made it from acorns that had not been leached enough to remove the tannin. It was tasty, but left an astringent, puckering aftertaste.

Some of the American trees still producing acorns are astonishingly large, but they were larger when people from the Old World came to this continent. When Europeans from Spain, Portugal, and England arrived in North America, they found giant trees, the likes of which existed only in the memories of their older countrymen. As Europeans had long since cut all of the large trees that grew in those countries, no one reaching the New World had ever seen anything resembling the enormous sky-fingering lofty towers of the Americas. People who saw those trees were delighted because they knew the wood could be used for building boats, houses, and other items essential for daily living. Moreover, they knew that people remaining in their homelands would pay fortunes for those wood resources. Immediately, they began felling the trees and opening the land to remake it in the image of human-scarred, unforested, barren, cultivated Europe.

Europeans figured that they had arrived in a “desert” in the New World, and they were terrified of wild areas. Although it has another meaning now, our word “desert” originally referred to anywhere people did not live. Immediately the newcomers began trying to make the “desert” into a “town”—a gathering of people in an enclosure or fortress. They knew that deserts not only contained tangible, potentially dangerous people whom they called “Indians,” but they also believed forests were inhabited by a plethora of other perils including trolls, goblins, spirits, ghosts, and similar malevolent entities. While “towns” were populated with many of those same shadowy hazards, other humans buffered the danger.

***Quercus.*** *Quercus chapmanii* .  
*Quercus geminata* . *Quercus minima* .  
*Quercus myrtifolia* . *Quercus*  
*virginiana* . All drawn by  
P.N.Honychurch.

They were not aware of it, but their actions were the same as those of fish in schools and birds in flocks. Gatherings reduce the chances of individuals being singled out for predation.

Many of the large trees the Europeans found in the New World were in genera they knew, such as *Abies* (firs), *Acer* (maples), *Betula* (birches), *Castanea* (chestnuts), *Fagus* (beech), *Fraxinus* (ash), *Juglans* (walnuts), *Picea* (spruces), *Pinus* (pines), *Populus* (poplars), *Quercus* (oaks), and *Ulmus* (elms). The newcomers to the New World were so greedy for the wood from these trees that large specimens like those they first encountered are today difficult to imagine, much less find. A visit to the Joyce Kilmer segment of the Nantahala National Forest in western North Carolina will give an idea of the size of those old originals. Some of the remaining tulip trees (*Liriodendron tulipifera*) there are so large that it takes three or more people linking hands to reach around their bases.

One of the most important genera to people then and now is *Quercus*, a Latin name applied since the days of the Roman Empire. Angel Oak on the Sea Islands near Charleston, South Carolina provides a glimpse of what those trees formerly were in the southeastern United States. Most of the other oak trees in North America are mere seedlings, no more than 200 or 300 years old.

*Quercus* in English is the “oak,” a word that appeared by A.D. 749, although spelling varied to include *oke* as late as the 1500s. The English name is related to Old High German *eih*, and Middle High German *eich*, a word now rendered *Eiche* in modern German. In Dutch, it is *eycken* or *eyckenboom* (oak tree). In Spanish, the trees are *encinos* (evergreen or “live” species) or *robles* (deciduous species). In Portuguese, the generic

term is *carvalho* (from the pre-Roman base word *carb* or *carv*, branched), and *roble* (from Latin *robore*, to be strong) is applied to only European *Q. robur*. To French speakers oaks are *chêne*, related to *chesne* as it was spelled by Fuchs in his *L'histoire des plantes* of 1550 (Meyer et al. 1999). Louisiana Houmas, who had lost their native language, said that *Q. virginiana* was *chêne vert* (green oak). Italians retain the Latin word only slightly modified into *quercia*.

In Hebrew oaks are *allon* or *elon*, both derived from the base-word *el* (god) (Zohary 1982). Oaks are called by that name because the trees are considered holy places where God speaks to mortals. Biblical legend has it that Abraham was visited by the angel of Jehovah under the branches of an oak (Lehner and Lehner 1960). Classical Greeks and Romans, including Pliny (A.D. 23–79) and Dioscorides (fl. A.D. 40–80), said *dryas*, and considered the oak the preferred tree of Zeus. Therefore, devotees of Zeus gathered under oak trees to worship, believing that, when their prayers were heard, the leaves rustled and birds began singing in the branches. That was how Zeus responded to the faithful (Lehner and Lehner 1960, Austin 1998a).

Celtic people also believed that spirits living in trees could be influenced by actions or ceremonies. The expression “knock on wood” (originally “knockwood”) is one of many Gaelic remnants in English. Knocking on wood, especially oaks, drew the attention of the spirits to the wish that had just been made (Panati 1987). One variant of the Celtic word for oak, *dair*, was the fourth letter of their alphabet, and an ancient holy site is the modern Irish city of Kildare (church in the oaks). In Gaulois, oak was *cassanus*, not Latin *quercus*, because as a sacred tree of the Druids, it kept its original name. Both *cassanus* and *quercus* are probably akin to Akkadian *kassu*, strong.

Many people throughout the Americas have generic names for oaks. Cherokees say *a-da:-ya*. In Náhuatl, they are *ahuatl* [*ahoatl*, *aoatl*]. Mexicans using that name also held the oaks in high regard, as witnessed by city names like *Ahuatepec* (oak hill), *Ahuachichilpa* (in the red oaks), and *Ahuatlán* (near the oaks). In Oaxaca, the Zapotecs say *yaga-yoo* [*yaga-xoo*] (*yaga*, tree, oak). Muskogean speakers, the Alabama, use the generic term *baya* [*bayo*]. Indeed, the genus is so important among indigenous people that Brown (2001) used it as an example of American nomenclature.

One measure of how important oaks were to southeastern tribes is reflected in the Muskogee names for them. Among the Seminoles in Oklahoma, there are ten species, each with distinctive names. Those are *cóskv* (post oak, *Q. stellata*), *kv'lv* (white oak, *Q. alba*), *kvlv'pe* (overcup oak, *Q. lyrata*), *lókcvpe* (red oak, *Q. rubra*), *lókcvpe-ldne* (live oak, *Q. virginiana*), *lókcvpe-lv'ste* [*lakcvpe-lvste*] (black oak, *Q. velutina*), *méskol-vpe* (water tree oak, *Q. nigra*), *meskólwv* (chestnut oak, *Q. muehlenbergii*), *sécv* (blackjack oak, *Q. marilandica*), and *tokvmáhv* (Spanish oak, *Q. falcata*).

In Florida, the only recorded indigenous names for oaks come from Muskogean people. Some Seminoles call the live oak (*Q. virginiana*) *lakcv cvmpv* [*lakcacámpa*, *alatka chumpa*, *lakchachaba*] (*lakcv*, acorn, *cvmpv*, sweet, Creek), and others say *okiciskí* [*okecheshke*] (*oki*, water, *ciskí*, oak, Mikasuki). Muskogee speakers in Oklahoma say *lókcvpe-ldne* (*lokcvpe*, acorn-tree, *lane*, yellow). The diminutive, but similar, *Q. elliotii* (= *Q. pumila*) is called *okiciskincó:cí* (*oki*, water, *ciskí*, oak, *inoci*, son, Mikasuki), while *Q. myrtifolia*, the myrtle oak, is *colokota:pí* (oak tree, Mikasuki) or *tohatka* (*eto*, tree, *hatka*, white, Creek). The most common tree on the Big Cypress Seminole Reservation in southern Florida is *Q. laurifolia*, the laurel oak. That wetland species is the *asaykaapi*

[*asayka:pi*] (*asayk*, acorn, *apt*, tree, Mikasuki), *asaykhiskoposkia* [*ashak heskoposhke, oshe huhka puske*] (*asayk*, acorn, *hiski*, leaf, *oposkia*, screech owl, Mikasuki), *asykhoomi* (*asayk*, acorn, *hoomi*, bitter, Mikasuki), and *mishcolabi* [*miskotapi, meskolwv*] (*méskolwv*, water oak, *vpe*, tree, Creek).

Oaks are cherished by people throughout the world for their woods and fruits, although some are more coveted than others. At least 30 species have been used for food and oil by people within the United States (Hodgson 2001). Live oak (*Q. virginiana*) is one of the most prized of American trees, and surely the most valued in the southeastern states. The species grows from Mobjack Bay, Virginia (southwest end of Chesapeake Bay), along the coastal plain and islands to Florida and along the shores of the Gulf of Mexico to northeastern Mexico, spreading farther inland in Texas than in other states (Diggs et al. 1999). In Texas, *Q. virginiana* introgresses with *Q. fusiformis*, formerly a variant, but now separated (Simpson 1988, Nixon 1997). Live oak is disjunct from Florida to Cuba (Sargent 1905, Leon and Alain 1946–1954).

Live oak wood is heavy, hard, strong, and tough—traits many think were passed to its worshipers and users. Wood is also close grained, light brown or yellow, and retains thin nearly white sapwood. *Quercus virginiana* was so valuable during the time of sailing vessels that the U.S. Navy obtained large holdings of live oak forests for exclusive use in the government's shipyards (Harrar and Harrar 1946). The large, massive, and arching limbs were highly sought after for making ship "ribs and knees." The wood was also used for construction and in manufacturing hubs, wooden cogs, furniture, and flooring. This was one of the most important trees to early European settlers in the southeastern United States, and wood from live oaks still is considered the best quality available for many items.

Dyes and paints were made by indigenous people from oak bark. Bushnell (1909) found that the Choctaw were using oaks only to make a red paint. They mixed bark from three or more oaks, including *Q. laurifolia* and *Q. virginiana*, and boiled the mixture until the liquid thickened. The bark was then removed and the liquid boiled again until it was thicker. Just before removing the hot mixture from the fire, a piece of pine pitch (*P. palustris*) was added, melted, and thoroughly mixed with the other liquid. This paint was then ready for use. Houma made a similar preparation, but also used it to stain baskets (Speck 1941). Bark was used sparingly by settlers in the tanning industry (Harrar and Harrar 1946).

Fruits of oak trees are acorns (*ak*, oak, and *corn*, seed, Anglo-Saxon). In Spanish, they are *bellota*, in French *gland*, in Italian *glanda*, and in Portuguese *glände*. All but the Spanish name are derived from the Latin *gland* (acorn). Some oaks produce tasty acorns that are eaten either raw or roasted; others have tannin that must be leached out before being eaten.

The seed crop from oaks is called "mast," from Old English *maest*, akin to Old High German *mast*, and Old English *mete*, meaning food. The word is related to "meat" (from Middle English *mete*, and related to Italian *madère*, and Greek *madaros*, to be wet) in the sense of food for humans and swine. A scribe of the 17th century wrote: "Acorns...(before the use of *Wheat-Corn* was found out) were heretofore the *Food of Men*, nay of *Jupiter* himself...till their Luxurious *Palats* were debauched. ...And Men had indeed *Hearts of Oak*; I mean, not so *hard*, but *health*, and *strength*, and liv'd naturally, and with things easily *parable* and plain" (from Fernald et al. 1958).

Indigenous Americans also had names for acorns. The Mixé of Oaxaca and Chiapas call the acorns *kook* [*shokiup*], the Otomí in Hidalgo say *métza* [*ndezâ*], the Zoque in Chiapas say *camay-cuy*, and the Tarascan of Michoacan use *taraquen*. The Catawba said *hitumq*'. The Cherokees called acorns *gule*. The Siouan people in Louisiana said *ay an'yá* (Biloxi) and *u'tu i'fhu* (oak seed, Ofo).

Muskogean tribes also had names for acorns; the Creek said *lakcv* [*lokcha, sockcha*] (Simmons [1822] 1973, Martin and Mauldin 2000), the Miccosukee *asayk* (Sturtevant 1955), the Chickasaw *nasi*' (Munro and Willmond 1994), the Choctaw *hane* (Crawford 1988) or *nusi* (Byington et al. 1915, Haag and Willis 2001), and the Alabama

*bayati* (baya, oak, *ati*, fruit, Sylestine et al. 1993). In Florida, the Timucua said *aha* [*aja*].

Indeed, there is a river in central Florida the Timucua called *ajano hibita chirico* (river of little acorns). The Seminoles also named places after the oaks, calling one *lokcha apopka* (*lokcha*, acorn, *apopka* place for eating, Creek). The first of these places we now call the Hillsboro River near Tampa, and the other is the Houston River in the Ten Thousand Islands of Collier County south of Naples. Live oak seeds were eaten by all tribes within its range (cf. Bartram 1791). Probably, it is live oak acorns in Timucua baskets that Frenchman Jacques Le Moyne drew from his visit to Florida in 1564–1565 (cf. Melanich and Milbrath 1989).

The first record of indigenous people using acorns to produce oil came from the de Soto expedition. The chroniclers reported people in the town of *Chiaha* (a Yemasee town) on the upper Tennessee River with “calabashes” (*Cucurbita*) filled with oil from nuts and acorns (Swanton 1939). Later, Capt. John Smith wrote: “the Acornes of one kind, whose barke is more white than the other, is somewhat sweetish; which being boyled halfe a day in severall waters, at last affords a sweete oyle, which they keep in goards to annoint their heads and joints. The fruit they eate, made in bread or otherwise.”

Harriot ([1590] 1972) was the first to record oil being made from acorns by North Carolina Algonquians. He wrote that there are “severall kindes of *Berries* in the forme of Oke akornes, which also by their experience and vse of the inhabitantes, wee finde to yeelede very good and sweete oule.” He selected one called *mangúmmenauk* [*mankwiminaki*, big nuts], “which beeing dried after the maner of the first sortes [chestnuts, walnuts, hickories], and afterwards watered they boyle them, & their servants or sometimes the chiefe themselues either for variety or for want of bread, doe eate them with their fish or flesh.” Presumably, the Powhatan acorns came from the oak Strachey called *poawamindg* (Harrington 1955). The Powhatans called acorn oil *monohominy* (Strachey [1612] 1953).

John Lawson, writing in the early 1700s about the Carolinas, found much the same. He remembered: “The Indians beat them [acorns] into meal and thicken their venison broth with them, and oftentimes make a palatable soup. They are used instead of bread, boiling them till the oil swims on the top of the water, which they preserve for use, eating the acorns with flesh meat” (Swanton 1946). Later Lawson paid special attention to live oak acorns (*Q. virginiana*) in the coastal zone. He found: “The acorns thereof are as sweet as chestnuts, and the Indians draw an oil from them, as sweet as that from the olive, though of an amber color. ...I knew two trees of this wood among the Indians, which

were planted from the acorns, and grew in the freshies, and never saw anything more beautiful of that kind.”

John Josselyn reported in 1672 that the Pilgrims in Massachusetts discovered baskets of *Q. alba* acorns hidden in the ground by the local Massachuset tribe in December of 1620. The New England settlers appropriated those seeds and prepared a palatable and nutritious dish of boiled sweet acorns. Rosengarten (1984) noted that acorns (*Q. alba*, which he emphasizes) contain 50.4% carbohydrates, 34.7% water, 4.7% fat, 4.4% protein, 4.2% crude fiber, and 1.6% ash. A pound of acorns is said to provide 1265 calories. Not only did native Americans eat acorns, they also used their oil for cooking and flavoring other foods such as hominy. We put butter on grits; they used acorn oil (see also *Carya*, *Juglans*, *Zea*).

Heavy crops of mast, or “mast years,” are irregular, and this helps spread the species. There are so many seeds during those seasons that, by simple chance, more are able to escape insects, birds, squirrels, and other animals that consume them. Many animals eat acorns; acorn weevils (Curculionidae) specialize on them. Gall wasps (Cynipidae) deform leaves, stems, and flower clusters with imitation plant hormones to secure their eggs and larvae. For many seasons I watched blue jays (*Cyanocitta cristata*) and boat-tailed grackles (*Quiscalus major*) gorge themselves on live oak acorns in southern Florida.

In England, the rural economy of an area was formerly measured in terms of the number of swine that its oaks could support. One entry in the *Domesday Book*, compiled on the orders of William the Conqueror about A.D. 1086, says of a certain village, “There is wood for forty swine,” and the village was taxed accordingly (Edlin and Mitchell 1985). In Europe, *Q. robur* was the species most prized for its acorns, and the American *Q. alba* is its New World equivalent (Fernald et al. 1958, Rosengarten 1984). The live oak runs a close second.

Oak bark and galls have been used to prepare permanent ink and medicines since antiquity (Meyer et al. 1999). Fuchs in 1542 recorded both uses and illustrated many galls on the leaves of *Q. robur*. Culpeper (1653) and other herbalists continued attributing medical properties to various parts of the oak. Florida and Oklahoma Seminoles came to the same conclusions (Sturtevant 1955, Howard 1984). Tannin is the known active chemical in oak medicines, and it has been shown experimentally to be antiviral, antiseptic, and antitumor, but also may be carcinogenic (see Simpson 1991 and Foster and Duke 1994 for divergent opinions).

Celtic and other people considered the oaks symbolic of strength. We still use that symbolism in the U.S. Army by presenting an Oak Leaf cluster for exceptional bravery. Our practice mimics that in the times of the Roman author Pliny (A.D. 23–79), when the oak symbolized bravery and a crown of oak leaves was a reward for outstanding military valor. Another European remnant is a Gaelic belief that oak leaves repel witches (Beith 1995, Vickery 1995). I wore a belt with oak leaves embossed on it for years and did not encounter a single witch. So, the charm obviously works.

# R

## ***Randia*: White Indigo-Berry**

(The genus honors the British apothecary and gardener Isaac Rand, d. 1743, who was the director of the Botanic Garden in Chelsea)

***Randia aculeata*. Drawn by  
P.N.Honychurch.**

According to my students, there is never anything distinctive about white indigo-berry (Florida). Even when I pointed out the short internodes resulting in clustered leaves, the reverse lance-shaped (oblanceolate) leaves, larger on the distal end and tapering to a pointed base, or the white flower, they still said it was not enough. So, I advised them to identify it by process of elimination until they learn it better. “If it is nothing else we have studied, try *Randia aculeata*.”

Linnaeus ([1753] 1957) named the plants *Randia*, but he did not originate the name. Instead, Linnaeus attributes *Randia* to Dutchman Adrian van Royen who took it from a De Jussieu, probably Bernard De Jussieu (1699–1776). Although the Linnaean Herbarium in London contains two specimens collected by Hans Sloane in Jamaica,

Linnaeus gave no indication that he had seen them. Instead, the basis for *R. aculeata* is a specimen from Jamaica thought to have been collected by Patrick Browne. The species name *aculeata* (prickly, Latin) refers to the short branches that are effectively spines.

Linnaeus probably also knew the species from plants cultivated in Leyden and recorded by Royen. Those plants too were apparently originally from Jamaica, where the plant's common name now is box-briar (Bermuda, Bahamas, Jamaica, Panama, Puerto Rico). Perhaps the name was in use in Linnaeus's time since "briar" and "*aculeata*" both allude to spiny plants. Indeed, the prickly nature of these shrubs has led to names through much of its range from southern Florida, Bermuda, the Bahamas, West Indies, Tamaulipas, and Sinaloa south to Cozumel Island, Ecuador, and Venezuela.

Other similar names in English are prickly bush [prickle bush] (Bahamas, Jamaica) and sticky bush. In French, it is a *croc à chien* (dog fang, Haiti). Spanish speakers have a greater variety of names. They call it the *agalla de costa* (coastal gall, Cuba), *escambrón* [*cambrón*] (big scale, Puerto Rico), *palo de espinillo* (tree of little spines), *punta real* (royal point or spine), or *serrasuela* (saw's at shoe-soles). Although *Randia* is called *bois de lance* (lancewood, French Antilles) and lancewood (Cayman Islands), the reference might be to the "lances" of the spines. The stems often are too small to make effective lances for hunting or fighting, although some are recorded up to 10 m tall and 22.5 cm in diameter (Roig 1945, Morton 1981).

Unless it is based on some unrecognized indigenous term, the name *papachilla* (Sinaloa; other spp. called *papache* in Sonora, from *papachos*, to cherish or caress) also seems to allude to the "loving" nature of the thorns in grasping passers-by. The name *peetschkitam* [*pehcitam*, *xpe'ech kitam*] (*peetsch*, dwarf, *kitam*, javalina, *Tayassu tajacu*, Maya, Yucatán, Belize) is an allusion to the spines. Apparently, the name compares the canines of these pig look-alikes to the spines on the plants. Both are dangerous to the unwary.

Several of the names have not been translated or only partly so. Those from Cuba and Puerto Rico may be based on Taino words. For example, *Randia aculeata* is *cabai-nacte* [*cabai nagte*] (Puerto Rico), *dragale* (*draga*, dredge, Cuba), *yamaguey* (Taino, Cuba), and *yamaguey de costa* (coastal *Randia*, Cuba). The word *yamaguey* differs only slightly from Camaguay, a province in Cuba, with both based on indigenous words. Or perhaps the province was named after these plants. The names *cracilla* (*crac*, crack, Mexico), *pitajoni bravo* (*pitajon*, big agave, *bravo*, wild, Cuba), and *pitajoni espinoso* (*pitajon*, big agave, *espinoso*, spiny, Cuba) all seem to be Spanish, but the allusions are uncertain. The onomatopoeic *crac* may refer to being stabbed by the spines. *Pitajon* probably refers to the spiny nature that resembles *Agave*. However, we are left wondering what kind of animal has a tail resembling some part of *Randia* in the name *raboe die kabasi* [*rabu di cabai*, *raboe die kabai*] (tail of *kabasi*, Dutch Antilles). The name *wakoera* [*wakura*] (Dutch Antilles) resembles an Arawak word as does *kabasi*, but nothing further has been found.

A number of names make understandable comparisons. To people in Cuba, these shrubs are like a *café cimarrón* (wild coffee). Some think *Randia* is more like a *Buxus* and say Florida boxwood, although others think that name should be confined to *Schaefferia frutescens* (Celastraceae). In Belize, they think the shrubs look like limes (*Citrus aurantiifolia*), and say bastard lime or wild lime; they also call them wild guava and wild okra. However, you might be able to make a fishing-rod (Antigua, Virgin

Islands) from the stems. Surely those who say *maíz tostado* (toasted corn, Colombia) are talking about something not obvious to the rest of us. In the southern Dutch Antilles, people make food beaters from branches, which they call *leele* [*lele*] (Bonaire, Curaçao), and the tree is *palu di lele* (food beater tree).

The Florida name white indigo-berry is analagous to indigo berry (Florida, Jamaica, Virgin Islands, Barbados), ink berry (Puerto Rico, Jamaica, Barbados), *tintello* [*tantillo*] (ink bush, Puerto Rico), and *tintero* (ink bush, El Salvador, Colombia). All those names refer to the fleshy berries, which have been used as substitute ink. Similarly, the names *palo de cotorro* (dove tree, Puerto Rico) and *petit coco* (little fruit, St. Barthélemy, Guadeloupe) refer to the fruits. However, *corallero* (red one, Colombia) makes no sense because the fruits are white outside and blue-black inside.

People not only note the edible fruits on *R. aculeata*, but they also consume them from other species. However, edibility is variable and some think the fruit a last resort. The related species *R. echinocarpa* has been described as bitter and overly sweet (Yetman and Van Devender 2002), and that pretty much sums up *R. aculeata*. In much of Mexico, the green astringent fruit is used to treat dysentery, while the ripe fruit is eaten as food. Ripe fruit also gives a blue dye (Standley 1920–1926).

One series of names surprised me by referring to the cross of the crucifixion of Christ. For 31 years, neither my students nor I ever noticed a similarity, but we were not guided by the Doctrine of Signatures. Nonetheless, from Mexico to Colombia the shrubs are known as *crucecilla de la costa* (coastal little cross, Sinaloa), *crucesita* (little cross, Mexico), *cruceta negra* (little black cross, Venezuela), *cruceto* [*crucito*, *crucete*, *crucilla*] (little cross, Tamaulipas, Veracruz, El Salvador, Columbia, Venezuela), *espina cruz* (cross spine, Cuba, Veracruz), and *palo de cruz* (cross tree, Colombia). Even the name *Juan de la Cruz* (John of the Cross, Cuba) makes that reference.

It might be the comparison to the cross that led people to begin using the shrubs as Christmas trees. When I first saw them being used in Santo Domingo, I could not believe my eyes. Vendors on the streets were selling leafless stems, some painted white and others silver, to be used during the Christmas season. They call them *árbol de Navidad* (Christmas tree, Puerto Rico), Christmas tree (Puerto Rico, Virgin Islands), *palo de Navidad* (Christmas tree, Puerto Rico), and *ramo de Navidad* (Christmas tree, Dominican Republic). In a tropical country with few conifers available, it only makes sense to substitute a local species during that Druidic-Christian festival (Austin 1998a).

Throughout its range in the Caribbean, *R. aculeata* is a medicine. Curiously, no medical use has been found in Mexico. Probably the best-known and most widespread application is to combat fever. The name chill-bush (Bahamas) refers specifically to that use. In Cuba, the sap is considered a hemostat (Roig 1945). Leaves are made into a bath for infected sores in the Bahamas, and leaves or roots boiled with *Senna mexicana* are used to expel the placenta after childbirth (Morton 1981). The name *María angola* (Angola Mary, Colombia) is likely an allusion to those uses.

Not only is white indigo-berry used during childbirth, but some have used it in earlier stages of relationships, as an aphrodisiac. The names *resuelesuele* (return money, Dominican Republic), *sota caballo* (substitute horse, Puerto Rico), and stiff cock (Bahamas) are allusions to that (Morton 1981). Sometimes the plant is used alone for this concoction, but on other occasions, the root is boiled with *Chiococca alba* or both are boiled with *Smilax havanensis*.

No chemical studies seem to have been made of *R. aculeata*. However, other species of *Randia* include saponins (triterpene, triterpenoid) (Saharia and Seshadri 1980, Murty et al. 1989, Sati et al. 1989, Sotheeswaran et al. 1989, Dubois et al. 1990, Dubois et al. 1990, Lemmich et al. 1995, Jansakul et al. 1999, Sahpaz et al. 2000), iridoid glucosides (Varshney et al. 1978, Sainty et al. 1982, Uesato et al. 1982, Sati et al. 1986, Davioud and Bailleul 1988, Sahpaz et al. 2000), coumarins (Bashir et al. 1986, Mallick et al. 1998), triacontanoic acid esters (Mallick et al. 1998), and some that are uncertain (Quershi and Thakur 1977).

Within the laboratory these chemicals suggest potential use as analgesics (Reanmongkol et al. 1994) and as anti-implantation compounds (Prakash et al. 1985). The chemicals are also hemolytic (Sotheeswaran et al. 1989) and cicatrizing in ulcers (Pérez et al. 1993). In addition, saponins in the fruits of *R. siamensis* have been used to poison fish (Jansakul et al. 1999). The iridoid glucosides are precursors of indole alkaloids and those from a number of plants have been shown to be analgesic, antimicrobial, antiviral, anti-inflammatory, wound healing, antioxidant, and cancer chemopreventive.

In one study the anti-inflammatory properties of iridoids “showed a significant effect on TXB2-release from calcium ionophorestimulated human platelets, with inhibition percentages slightly lower than the reference drug ibuprofen” (Bermejo et al. 2000). So, if you do not have a commercial preparation with ibuprofen handy, you could always try eating some white indigo-berry. Who knows? It might work.

### ***Ranunculus***

(From Latin *rana*, frog, plus *-unculus*, small; applied to these plants by Pliny, A.D. 23–79)

***Ranunculus abortivus*.** a. Young plant, b. Plant in flower, c. Mature receptacle bearing seeds, d. Seeds. From Buchholtz 1968.

*batrachion* (frog, Greek)

*buidheag* (little yellow one, Gaelic)

buttercup (this is a comparatively late name for *Ranunculus*, having been in use by 1777; before that the plants were known as “butterflower,” “king cups,” and “gold cups”)

butterflowers or gold cup (in use by 1578, when Henry Lyte translated Dodoens’s 1554 herbal with “Some do also name it...in Englishe Gold-cuppes, Gold-knoppes, and butter-flowers”)

crowfoot (in use by about A.D. 1440 for *Ranunculus*, particularly those with divided leaves; subsequently extended to the entire genus; the comparison is with the foot of the carrion crow, *Corvus corone*; *Hahnenfuss* (cocksfoot or crowfoot, German))

king cup (a name used by Turner in his *Herbal* of 1562 where he equated it with crowfoot)

*llygad drill* (Welsh)

meadow-bloom

pilewort (Turner, in his *Names of Herbes* of 1548, called *R. ficiaria* the “fygwurt,” where “fig” at that time was the name for piles)

*ranoncule* (from *ranunculus*, Quebec); *ranuncolo* (Italian); *ranúncolo* (Spanish)

*Scharbockskraut* (scurvy herb, German)  
*soleie* (*sol*, sun, *eie*, owned, Norwegian)  
 spearwort (in use by 1387, when a book published in London said,  
 “sperwort, *calidus est et siccus in quarto gradu*” [it is dry and hot in the  
 fourth degree])  
 yellow-weed

***Ranunculus abortivus*** (abortive, i.e., with reduced styles and petals)  
 [kidney-leaf, little-leaf] buttercup  
 chicken pepper  
 [small-flowered, smooth-leaved] crowfoot

Although we credit Linnaeus ([1753] 1957) with the creation of *Ranunculus*, the name had been in use since the time of Pliny (A.D. 23–79). That ancient application is still reflected in the Romance languages as *ranoncule* (French), *ranuncolo* (Italian), and *ranúncolo* (Spanish). Fuchs (1542) also used the Greek name *batrachion* (frog) for *Ranunculus*.

Europeans knew these plants well before they arrived in the New World. There were multiple uses and beliefs associated with the genus. Farmers in some areas were convinced that cattle eating these yellow-flowered plants in the spring passed the color along in their golden butter. Some cattlemen even rubbed the flowers on their cows' udders and hung the plants over the barn door to add color to the cream (Coffey 1993, Vickery 1995). In the Inner Hebrides, *R. flammula* was used as a substitute for rennet in cheese making (Vickery 1995).

The belief that the gold of the flowers was passed to cream and butter was erroneous. Sap from the plants is acrid and grazing animals avoid them when possible. Indeed, the sap is so caustic that Fuchs wrote in 1542: “Healthy scoundrels and beggars abraid their legs and arms with this plant in order to extort alms shamelessly, and by this trick increase their gain” (Meyer et al. 1999).

Considering the acrid nature of the plants, it is difficult to believe that the Cherokee cooked and ate the leaves as greens (Hamel and Chiltoskey 1975). However, Fernald et al. (1958) had discovered edibility and experimented with *R. bulbosus*. They found that John Lightfoot, in his *Flora Scotica* of 1777, had experimented before them and written, “not withstanding this corrosive quality, the roots when boiled become so mild as to become eatable.” Fernald et al. (1958) reported that the round bulbs, after having overwintered, were mild and sweet in the spring. When thoroughly dried they lost their acidity.

Vogel (1970) found that the Illinois-Miami treated gun or arrow wounds with the crushed root of a *Ranunculus*. No species was indicated; perhaps several were used. The crushed root was dissolved in warm water, and apparently was intended to prevent infection through its caustic or vesicant activity. Farther south, the Cherokee used small-flowered crowfoot in a poultice on abscesses, for “thrush” (*Candida*), as a sedative, and to relieve sore throat (Hamel and Chiltoskey 1975). The Iroquois took a decoction to treat epilepsy, blood disease, sore eyes, stomach trouble, stiff muscles, snakebite, and toothache. They also found it emetic, and used it to counteract poison and to dry up smallpox sores. The Meskwaki used the roots as a styptic to stop nosebleed (Vogel 1970).

Several other species were used for similar purposes in the eastern forest region by the Abnaki, Montagnais, Ojibwa, and Potawatomi (Smith 1933, Vogel 1970, Moerman 1998).

In 1751, John Bartram wrote that a decoction of *R. abortivus* was considered a remedy for inveterate syphilis (Coffey 1993). However, it was the introduced European *R. bulbosus* that became official in the U.S. Pharmacopoeia between 1820 and 1882. That species was considered acid, and it was applied externally as a counterirritant (Vogel 1970). Porcher (1863) recommended either *R. scleratus* and *R. repens* as a rubefacient. Of *R. scleratus*, he added, "It has been administered with success in asthma, icterus, dysuria, rheumatism, pneumonia, and fixed pains. When it acts as a vesicant, it has not the disadvantage of producing strangury." Millspaugh (1892) gave much the same information, but noted that *R. acris* and *R. bulbosus* have similar properties.

Fernald et al. (1958) called the acid principle in *Ranunculus* anemonol. However, Turner and Szczawinski (1991) explain that the acid compound is protoanemonin, an enzymatic breakdown product of the glycoside ranunculin. When the plants are dried, the protoanemonin becomes the innocuous anemonin. Foster and Duke (1990) warn that the acid chemicals are known for "causing intense pain and burning of the mouth, mucous membranes; blisters skin."

### *Rapanea*

(Jean Baptiste Christophore Fuseé Aublet took the name from the French Guiana indigenous *rapana*)

***Rapanea punctata*. Drawn by  
P.N.Honychurch.**

***Rapanea punctata*** (dotted, in reference to the leaves)

*akcomakáhka:phatki* (white tobacco-seasoning tree, Mikasuki; from *akahke*, tobacco, *hatki*, white); *hici:apa:kahátki* (*hici*, tobacco, *vpakv*, seasoning, *hvtke*, white, Creek)

*bádula* (Puerto Rico)

*caca-ravat* (*caca*, feces, *ravet*, rat, the same name is used for *Myrica*, *Forestiera*, and *Trema*, Guadeloupe, Martinique)

*camagüilla* (from Taino *yamaguay?*, Cuba)

*canelón* (big cinnamon, Argentina); *fuella canelle* (cinnamon leaf, Haiti)

*chagualito* (Colombia)

colicwood (Florida)

*cucharo* (spoon, Venezuela)

*dakara* (Arawak, for *R. guyanensis*, Guyana, Suriname)

*fuella* (variant of *feuille*, leaf, Haiti)

*kunaporan* [*koonaparan*] (Carib, for *R. guyanensis*, Suriname)

*mamayuelo* (little mamey, Puerto Rico); *mameycillo* (little mamey, Venezuela)

*manteco blanco* (white butter, Venezuela)

myrsine (myrtle, Greek *Myrtus*, a related genus, Florida)

*palo de sabana* (savanna tree, Dominican Republic)

*poève* (perhaps *poêle*, a pall at a funeral, Haiti)

Lamarck called this small tree *Sideroxylon punctatum* in 1794, thus placing it in the wrong family. It was not until 1969 that Cyrus Longworth Lundell (1907–1994) discovered the problem and moved it to *Rapanea*. The number of species in the genus is not clear as Mabberley (1997) considers it part of *Myrsine*, as have most other recent biologists.

As their names suggest, the Seminoles used this to extend their tobacco (Sturtevant 1955). No other uses are known, but the name “colicwood” indicates former use as a treatment for colic. Some separate the Greater Antilles plants from *M. guianensis* or *R. guianensis*. If that is done, the names from South America should be stricken.

***Reynosia***

(In 1866, Grisebach named this genus for Alvaro Reynoso, a Cuban chemist and agriculturist who died in 1888)

***Reynosia septentrionalis*** (pertaining to the north)

Caicos [darling] plum [dollen plum] (Florida, Bahamas)

red ironwood (Bahamas)

It was not until 1899 when Urban described this species, with one of the specimens he cited having been collected in Florida. All of the other 17 species are all in the Caribbean except for 1 in Central America (Mabberley 1997). Fruits of many species are edible.

***Reynosia septentrionalis*.** a. Branch with flowers, b. Detail of leaf axils and terminal bud, c. Leaf apex showing midrib extension, d. Flower, side view, e. Flower, from above, f. Flower, longitudinally dissected, g. Floral diagram, h. Branch with fruits. *Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

In the Bahamas the trunk is scraped and boiled into a decoction used to stop diarrhea (Eldridge 1975, Morton 1981). The decoction is also used for “weakness.” Fruits are edible, but make some people dizzy if there is nothing else in the stomach (Morton 1968, 1981).

### ***Rhabdadenia***

(Swiss botanist Johannes Müller Argoviensis, 1861–1920, named this with Greek *rhabdos*, a rod or stick, and *aden*, gland, possibly a reference to the slender fruit)

***Rhabdadenia biflora*** (with two flowers)

*bejuco de manglar [de mangle]* (mangrove vine, Dominican Republic, Puerto Rico); mangrove [swamp] vine (Florida, Bahamas, Puerto Rico, Panama, Belize)

*caoutchouc* (rubber, alluding to the latex, Hispaniola); *palo de leche* (milk tree, Dominican Republic); rubbervine (Florida)

***Rhabdadenia biflora*.** a. Apex of flowering stem, note that the inflorescence is not axillary, b. Flower, from above, c. Flower tube, longitudinally dissected, d. Floral diagram, e. Fruits. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

*clavelito* (little carnation, Colombia); *clavelitos de manglar [de sabana]* (little mangrove [savanna] carnation, Cuba)  
*tataku* (Miskito)

Jacquin named these climbers *Echites biflora* in 1760. Subsequently, the plants were studied for the *Flora Brasiliensis*, and Swiss botanist Johannes Müller Argoviensis, who did the family for that book, moved the species to *Rhabdadenia*. Since then two other species have been found in tropical America (Rosatti 1989, Mabberley 1997).

The acrid juice is purgative and poisonous and produces blisters on the skin (Standley 1920–1926, Roig 1945). Taken internally the latex inflames the entire alimentary canal, although it is used to kill troublesome feral animals (Roig 1945). Mabberley (1997) indicated that it contains alkaloids.

### *Rhamnus*

(Pliny, A.D. 23–79, used *rhamnus*, the ancient name “for a prickly plant,” said to be based on Greek *rhamnos*; according to Millsbaugh, the name is from Gaelic *ràmh*, branching; Quattrocchi thought the name was from Greek *rhabdos*, a stick; akin to Akkadian *rapasu*, to beat, Sumerian *rab*, stick, branch)

***Rhamnus caroliniana*.** From Sargent  
1905.

buckthorn (“buck” referred originally to either the male deer or goat, although now it is applied to a number of caprids; the word is perhaps of Germanic origin, from Old English *buc* and *bucca*, or maybe from Gaelic *boc*; combined with “thorn” dates from ca. 1578, and is a translation of Latin *cervi spina*); hart’s-horn (cf. Culpeper 1653)

*cervispina* (from Valerius Cordus in 1561); *espino cervical* (deer’s horn, Spanish); *spino cervino* (deer’s horn, Italian)

Christes thorne (by Turner in 1548 and then in John Gerarde’s *Herball* of 1597); *Kreuzdorn* (cross thorn, German)

frangula (from Latin *frangere*, to break, first used by Rembert Dodoens in 1554); *frangula* (from Latin *frangula*, Portuguese)

*geitved* (goat wood, Norwegian)

herb-ivy [herb-eve] (from Culpeper 1653)

*nerprum* [*nerprun*] (from Latin *niger prunus*, black plum; only in Gallo-Roman, French)

*ohicta* (Onondaga)

ram of Lybia (John Gerarde’s *Herball* of 1597); ram-thorn (from 1633 in Thomas Johnson’s enlarged version of Gerarde’s *Herball*)

rhamn (called “rammyn or thefthorne” first in English about A.D. 1340; in 1388 glossed “rhamne” and translated “theve [thief] thorn”)

***Rhamnus caroliniana*** (of Carolina) (= *Frangula caroliniana sensu* Kartesz 1994, Moerman 1998, Diggs et al. 1999)

bog-birch

[alder-leaf, Carolina, southern, yellow] buckthorn

Indian-cherry (because the fruits were eaten by indigenous tribes, as medicine?)

polecat-tree (“polecat” from Middle English *polcat*, *pulcat*, where *pol* or *pull* probably came from Old French *poule*, chicken, and *cat*, the feline; first used A.D. 1320 for the animal, *Putorius foetidus* of Europe)

yellow wood [yellowwood]

When Europeans arrived in the New World, they were greatly enamored of plants called “buckthorn” or “*espino cerval*” Those plants had been medicines since at least the 1st century A.D. when Pliny talked about them. The Greek physician Galen of the 2nd century A.D. also praised the plants as giving protection from witchcraft, demons, poisons, and headaches (Dobelis 1986). It is surely significant that the Temple of Nemesis is at the Rhamnus ruins on the coast northeast of Athens and Marathon in Greece (Baumann 1993).

The variety of common names used between the time of Pliny and the discovery of the New World is partly due to the rich history of mixing pagan with Christian views. The oldest of the names alludes to “branches,” regardless of its linguistic stock. Languages as diverse as Gaelic, Greek, and Sumerian make that notation, surely because the bark was taken from branches for use in medicine. Even today, the connection with pagan spirits remains in the common name *trollhegg* (troll hedge or garden) for *R. frangula* in Norway (Mossberg and Stenberg 1994). With the rise of Christianity, its leaders incorporated this sacred pagan plant into their pharmacopoeia by giving it names like “Christes thorne” and “*Kreuzdorn*.” Europeans knew two important species now called *R. frangula* and *R. cathartica* (Culpeper 1653, Millspaugh 1893, Dobelis 1986).

Florida’s buckthorn was described by Thomas Walter (1740–1789), a Charleston planter, in his *Flora Caroliniana* published in 1788. That same year, Frenchman Charles-Louis L’Héritier de Brutelle described *R. alnifolia* from eastern Canada. Those two species were described after Spanish priests in California dubbed a local plant the *cáscara sagrada* (holy bark) in 1777. Coon (1974) said that the priests gave the plant that name because of the high regard the local tribes had for it as a medicine. Clearly, it was highly regarded by numerous groups because Moerman (1998) listed 30 tribes that used it.

It was not until 1825 that botanists described the Pacific coast plants as *R. purshiana*. Although Europeans were so enthusiastic about their buckthorns that they introduced both species into the eastern United States where they became naturalized, they were reluctant to accept the American plants as medicines. It was not until 1877 that American and European physicians began accepting *cáscara sagrada* as an effective medicine (Dobelis 1989). Once physicians admitted *cáscara sagrada*, it became part of the U.S. Pharmacopoeia in 1894, and it is now the most commonly used laxative in the world (Heiser 1993). However, see also Bown (1995) and Duke et al. (2002).

I grew up hearing people talk about taking “cass-cáre-ah,” and the older people considered it a remedy for whatever ailed them. It was long after I learned to speak

Spanish that I connected “cass-cáre-ah” with *cáscara* (bark), and then with *cáscara sagrada* (holy bark). My parent’s generation was dosed with that plant weekly as a general “preventative” for everything. Authors of most literature on the time and topic call *cáscara* a “tonic.” However, those who actually were obliged to take it have other, more derogatory terms for *cáscara*—and its impact on the alimentary canal.

Lewis and Elvin-Lewis (1977) recognize three classes of purgatives. The first works by adding bulk, and *Plantago psyllium* is probably the best known of that category. Their second category includes lubricants, such as “mineral oil” (liquid paraffin). *Cáscara sagrada* is in their third category where the chemicals irritate the lining of the intestinal walls. The active compounds in *cáscara sagrada* and other *Rhamnus* are anthraquinone glycosides, particularly cascarn (Lewis and Elvin-Lewis 1977, Turner and Szczawinski 1991).

Indigenous Americans did not have the same preoccupation with their bowels as did Europeans, but they still used *Rhamnus* as medicine. One indication of the difference in views is that only two tribes are known to have used *R. caroliniana*. The Creeks took an infusion of the wood to relieve jaundice (Swanton 1928a). Oklahoma Delaware took a decoction of the bark to “remove bile from the intestines,” and as an emetic and cathartic (Moerman 1998). Since the plants did not grow in the original homeland of the Delaware in New Jersey and Pennsylvania, uses must have been learned after their removal.

California tribes used *cáscara sagrada* as a dye (Moerman 1998). No records have been found for eastern tribes using *R. caroliniana* as a dye; however, Tull (1999) was assured that it provides dark brown and yellow colors. Cannon and Cannon (2003) record dyes obtained from several *Rhamnus* species, including yellows that Jews were forced to use to color their clothes to distinguish them from Christians in the Middle Ages. Presumably, the chemicals of the Old World species forming the dyes are the same as in American plants. Cannon and Cannon (2003) noted flavonols, including kaempferol, rhamnetin, rhamnocetrin, and quercetin, and the anthraquinones, alaterine, frangularoside, rhamnicoside, often with a dominance of emodin.

Some sources record the fruits of Carolina buckthorn as edible. For example, Tull (1999) noted that she had been assured that the fruits could be eaten, but after tasting them, she concluded that they were inedible. Certainly, nothing about the flavor is likely to induce people to eat many of them. While fruits are attractive reds or purples, the flesh is bittersweet. Fernald et al. (1958) noted that some *Rhamnus* fruits are “said to be palatable,” while others are poisonous. Dodoens in the 1500s said that the berries “be not meete to be ministered but to young and lustie people.” Fernald et al. (1958) have an even less favorable quote from New England where a young boy remarked, “Them is terrible things for the guts.”

### *Rhexia*

(From Greek *rhexis*, breaking or rupture, for “the breaking or bursting forth of the entrails of victims”; a name used by Pliny, A.D. 23–79, for some Boraginaceae reputed to be useful in curing ruptures)

deer-grass [deergrass] (OED 1971 says a name in use by 1866; however, Porcher 1863 had written earlier, “Deer grass... The leaves of this plant have a sweetish, acid taste; and are eaten with impunity. Deer are said to be fond of them”)

Maid-Marian (by 1525 the name of a female personage in the May-game and Morris-dance, held on the first of May; later the female companion of Robin Hood; presumably used for these plants because they begin flowering in May)

meadow-beauty [meadow beauty, meadowbeauty] (in use by 1866; unexplained unless it may be taken literally)

sorrel (used by Porcher 1863; this must be a comparison with *Rumex*, which is typically called sorrel because of the sour taste)

***Rhexia virginica*** (from Virginia)

handsome-Harry [handsome Harry] (used by John K.Small in 1933)

[common] meadow-beauty

Robinhood (name used for the plant by Manasseh Cutler in 1785, maybe because of the alternate name Maid-Marian)

vinegar wood (an allusion to the sour taste)

Virginia soapwort (John Clayton wrote “soap wood” in the 1730s, but he compared the English to Latin *saponaria*, also called soapwort)

Linnaeus ([1753] 1957) had not seen living plants of *Rhexia* when he adopted the genus from Jan Gronovius. In his *Flora Virginica*, Gronovius called these herbs *Rhexia calycibus glabris* (*Rhexia* with a glabrous calyx). Linnaeus shortened that to *Rhexia virginica*. Either Linnaeus was impressed with the broken fruit on the specimen, or he had learned how easily the petals fall from the flowers. In the early 1970s, one of my students assumed that the name *Rhexia* was based on “wrecks-easy.” She was almost correct. Although the flowers may be in their prime when stems are picked, the petals usually fall between that moment and closing the press to make herbarium specimens, no matter how short the interval.

This North American genus contains 13 species (James 1956, Kral and Bostick 1969). *Rhexia cubensis* extends into the Caribbean, being found in Cuba, Hispaniola, and Puerto Rico (Leon and Alain 1946–1953, Liogier and Martorell 1982).

*Rhexia virginica* grows from Nova Scotia to Ontario, and south to Georgia, Alabama, Tennessee, and Missouri. Although Correll and Johnston (1970) specifically excluded *R. virginica* from Florida, the plants do grow there. Indeed, Wunderlin (1998) says that it is “Frequent; northern cos.” On his Web site, he shows the species from Escambia to Flagler across the whole tier of Florida counties.

Fernald et al. (1958) wrote that these small herbs were “too beautiful and local a plant for general use as a food, but in regions where it abounds it furnishes a pleasant salad, the leaves having a sweetish and slightly acid taste, while the tubers are pleasantly nutty in quality.” They continue that, probably, “other species of the genus have similarly palatable qualities.” Related to edibility is the use by the Montagnais of eastern Quebec and Labrador, who made the stems and leaves into a sour beverage. Micmac of New Brunswick and Nova Scotia and vicinity used it to clean the throat (Moerman 1998).

Porcher (1863) also considered the leaves edible. Unfortunately, there does not seem to be much other information on the edibility of *Rhexia*.

### ***Rhizophora*: Red Mangrove**

(From Greek *rhiza*, root, and *phoros*, bearing, in reference to the aerial roots)

When Europeans first went from their temperate homes into the tropics, they found plants and animals that were incredible. Those lucky enough to return home brought fantastic tales to their homebound compatriots. One of those tales familiar to everyone is about mermaids. A story that has not been made so popular involves red mangroves—trees that seemed to be walking out into the edge of the sea. One of the first comments in English about these trees appeared in

***Rhizophora mangle*. Drawn by  
P.N.Honychurch.**

1613 with “Amongst all the rest there growes a kinde of tree called Mangrowes, they grow very strangely, & would make a man wonder to see the manner of their growing” (OED 1971).

Herbalist Johanne Bauhin wrote in 1650 that the tree was the *Mangle pyrifoliis* (thicket with pear-shaped leaves). However, Everardus Jacobus van Wachendorff (1702–1758), studying cultivated plants in Holland, coined the name *Rhizophora* in 1747.

Linnaeus liked that, and adopted it in the name we currently use—*Rhizophora mangle*. The species name *mangle* means simply “thicket.” Most common names still incorporate *mangle*, or translate it into a word meaning the same.

It seems odd, but people throughout the world, regardless of their languages, have a tendency to assign colors to the various kinds of mangroves. Inexplicably, they do not agree on what color a particular species is. In English, *R. mangle* is mostly red mangrove (Florida to Panama), although sometimes that becomes roode mangrove (Guyana) in Creole. The name “red mangrove” may have been first applied by part-time botanist and full-time pirate William Dampier in 1697. To others, it is simply mangrove (USA) or old lady mangrove. However, some think it should be black mangrove (Guyana), a name mostly given to *Avicennia germinans*.

In Spanish, *R. mangle* is simply *Colorado* (red, Belize), *mangle Colorado* (red mangrove, Tamaulipas, Veracruz, Tabasco, Oaxaca, Guerrero, Caribbean, and south to Panama), *mangle rojo* (red mangrove, Venezuela), or simply *mangle* (mangrove, Baja California, Sonora, Dominican Republic south). Others think of it differently, and say it is the *mangle caballero* (gentleman’s mangrove, Costa Rica), *mangle dulce* (sweet mangrove, Baja California, Venezuela, Peru), *mangle de chifle* (whistle mangrove, Puerto Rico), *mangle gateador* (cat-colored mangrove, Costa Rica), or *mangle piñon* (pine mangrove). Still others note the adventitious roots and say it is a *mangle injerto* (grafted mangrove, Ecuador). Those with a more utilitarian view say *mangle salado* (salty mangrove, Panama, Venezuela), *mangle tinto* (dyer’s mangrove, Veracruz), or *mangle zapatero* (shoemaker’s mangrove, Puerto Rico). Even in Spanish, some say it is the *mangle prieto* (black mangrove).

French speakers are mostly agreed it is a *mangle rouge* (red mangrove, Guadeloupe), *manglier rouge* (red mangrove, Haiti, Guadeloupe), or *palétuvier rouge* (red mangrove, French commerce). Often that is shortened to *manglier* (mangrove, Haiti) or *palétuvier*. In French, too, it is *mangle noir* (black mangrove, Guadeloupe). Others think the propagules resemble candles, and say *manglier chandelle* (candle mangrove, Guadeloupe). Spanish speakers also say *candelón* (big candle, Veracruz, Colima, Sinaloa).

Brazilians say *mangue vermelho* (red mangrove), *mangue verdadeiro* (true mangrove) or just *mangue* (mangrove). They also describe the propagules as *mangue de pendão* (hanging mangrove, Brazil). Like people speaking Spanish, they note uses with *mangue de sapateiro* (shoemaker’s mangrove), and *mangue-tan* (tanning mangrove). Sites where the trees are thick are a *mangarabeira* [*mangarobeira*] or a *managaixi* (both, place of mangroves).

In the old Dutch colonies, the trees are *romangel* (red mangrove), *mangro* (Sranan, Suriname), or *zwamp-mangro* (swamp mangrove, Suriname). People also allude to the extraction of tannin for curing animal hides with *mangel tan* (tan mangrove, Dutch Antilles), although *taan* is the continental spelling of the word. These same people have some wonderful deviations from the norm. They note that these coastal forests are a *duivenhout* (dove wood, Suriname), where many birds roost. They also allude to the many adventitious roots with *duizendbeen-boom* (thousand leg tree, Suriname) and *duizenhout* (thousand wood, Suriname).

Indigenous people have a multitude of names for these useful trees. Several may be simple terms with no translations. These include names from Sonora, Mexico, such as

*canaro* (Mayo), *nahnawa'ara* (Yaqui), and *pnaaoej-xnazolcam* (Seri). In South America, they are *kakoetji-roe* (Guyana), *kakutiru* [*kakutira*] (Arawak, Guyana, Suriname), *kunapo* [*konapo*] (Carib, Guyana, Suriname), and *purgua* (Venezuela). To people on the Panama-Colombia border they are *aili kinnut* (Cuna).

The Maya are direct and say *tab-ché* [*tap-ché*, *xtabche*] (*tab*, salt, *ché*, tree, Maya, Yucatan, Belize). In Brazil, that is not enough. Brazilians say *apareiba* (place that receives waves?), *canaponga* (*cana*, cane or grass, *ponga*, put), *guapereiba* [*guaparaiba*, *guarapahy*] (edge of a depression, Tupí), and *ratimbo* (*rã*, frog, *timbo*, white or ash-color, Tupí).

To the Seminoles of southern Florida, the trees are *ahilo:ckitiscí* (*ahí*, tree, *kitisci*, red, *lo:ci*, black, Mikasuki), and *tolastica:tí* (*eto*, tree, *lvste*, black, *cvte*, red, Creek). Perhaps the trees were more important to them in the past when they clothed themselves with buckskins cured with the tannin from *Rhizophora*. However, by the time Sturtevant (1955) worked with them, they remembered no other uses.

Early visitors to the Caribbean noted the utility of these trees, the oysters that grew on their roots, and the fish that hid in their prop-roots during high tides. Wood was used to make oars, fuel, building wharfs and docks that resist attack by *Teredo* mollusks, huts, houses, doors, and window frames. Little and Wadsworth (1964) record that the sapwood is light brown, while the hardwood is reddish brown or dark brown. Wood is hard, heavy (specific gravity 0.9 to 1.2), and durable in the soil but susceptible to dry-wood termites. DeBrahm ([1775] 1971) said that the wood "is very close and fine grained, after cut and dried grows as hard and near the Colour of Lignum sanctum [*Guajacum*], takes a very fine Polish." He also thought the coals of the wood "burn clear, and leave little or no Ashes."

However, most of all, the indigenous people and the Europeans found the tannins in the leaves and bark valuable for making leather. Natives and newcomers knew that adding salts of copper or iron to the bark would yield olive and brown dyes. Panamanians made a red dye from the young shoots, and DeBrahm ([1775] 1971) recorded that Morocco leather was made with red mangroves.

Oviedo noted that the native people ate the fruit. Supposedly, "It is tawny and within is a marrow or heart which the Indians eat when they can find no better fruit (for it is somewhat bitter), and they say it is wholesome" (translation from Standley 1920–1926). Far away in Sonora, Mexico, the Seri also ate the fruits (Felger and Moser 1985). Perhaps the practice formerly was common.

Julia Morton (1968b), who would eat almost anything, considered the fruit bitter and "not good." She also tried smoking the propagules as cigars, made tea from the leaves, and used the twigs as toothbrushes.

Hans Sloane (1707–1725) wrote that the blacks in Jamaica made cords from the bark. After removing the bark with knives, they beat it "with a mallet until the first gross one be separated from the second: of the more gross is made cords of other britches, for the negroes and slaves." Others recorded that they also made ropes of the fibers (Grimé 1976).

Medicinally, the bark is used as a febrifuge, to stop hemorrhage, and as a remedy for sore throat. *Curanderos* in Belize still use a decoction of the bark to treat sores, skin problems, leprosy, and swellings (Arvigo and Balick 1993). Morton (1981) included remedies for asthma, syphilis, elephantiasis, diarrhea, dysentery, leukorrhea, gonorrhea,

bed-wetting in children, backache during pregnancy, and to cure fish poisoning (presumably ciguatera).

Laboratory experiments indicate that the bark extract is antibacterial (Rojas-H. and Coto-P. 1978, Melchor et al. 2001), helps heal ulcers (Perera et al. 2001), aids in controlling diabetes (Alarcon-A. et al. 1998), is antifungal (Cáceres et al. 1993), and helps enhance immunity (Rao et al. 1971). Moreover, the extract is insecticidal (Williams 1999).

When Frank Hamilton Cushing excavated the long-abandoned and buried Calusa village on Marco Island in 1896, he found that the houses had been built on pilings over the water in a mangrove swamp (Gilliland 1975). He was convinced these people were a semi-aquatic culture, like those in Venice, or those off the coast of Venezuela (meaning little Venice). He dubbed one part of the site “Court of the Pile Dwellers.” The unique artifacts he recovered had been covered and then preserved in mangrove peat, an acid, anaerobic medium.

Memories of my first visit to the Marco Island region in the early 1970s are still vivid. As I stepped out of my car to examine bayside vegetation, my white trousers immediately turned black. Mangrove mosquitos were so abundant that my clothes and skin looked as though they were covered with black hair, and my skin burned from their bites. How did the Calusa thrive and practice their arts there without these tiny vampires draining their blood?

## *Rhus*

(The ancient name used by the Greek philosopher Theophrastus, 372–287 B.C., probably based on Greek *rhodos*, red, from the tannin in the stems and the edible red fruits)

*bati* (Choctaw); *bati'* (Chickasaw)

sumac (from Arabic *summaq*); *sommacco* (Italian); *sumac* (French); *Sumach* (German); *sumagre* (Portuguese); *zumasque* (Spanish)

*Rhus aromatica* (fragrant)

*akko,*

*hoyvnecv rakko* (*honece*, wild, big; see Martin and Mauldin 2000; compare with *Salix humilis* or *mikko hoyvniyv*)

polecat-bush

[fragrant, lemon] sumac

*Rhus copallina* (from *copal*, because of a copal-like resin from the stems)  
*añil de pinar* (pine-tree indigo)

*aso:kóta:pî* [*ashooket aape*, *asookotaapi*, *açokotapi*, *hekotaape*] (*ashooket*, berry, *aape*, tree, Mikasuki); also called *asó:kótî* or *asó:kotó:bî* (*asó: kótî*, berry, *có:bî*, big)

[black, dwarf, flame-tree, mountain, shining, winged, wing-rib] sumac (USA); shoemake [shumaker] (Carolinas, Florida); *sumaque* (from Arabic *summaq*, Mexico)

*tvwv* [tawâ, tawa, tv'wv, cúwv] (Creek, Muskogee); *tabó* (Koasati); *tauwv Ivste* [tawa lasti] (tvwv, sumac, *Ivste*, black, Creek, Muskogee)

***Rhus glabra*** (smooth)

*bashukcha* [basho'nkchi, bushukcha, bushucha] (said to mean "the sumac that bears the purple bud," Choctaw, Mobilian; maybe from *bashih*, to wither or fade, an allusion to the flowers?, *okchakki* [okchakko], blue-green, Choctaw); *bashanchik* [homma', tohbi'] ([red, white] sumac, Chickasaw)

*chan-zi* (*chan*, wood, *zi*, yellow, Dakota); *haz-ni-hu* (*haz*, fruit, *hu*, plant, Winnebago); *ni-ni'-gah hi* [kin-ne-ne-kah] (*ni*, live, *ni*, water, *hi*, plant, Osage; akin to *kinnikinnick*); *glikénican* (Delaware; akin to *kinnikinnick*)

*maw-hko-la* (tobacco mixture, Kiowa)

***Rhus. Rhus copallina*** . From Sargent 1905. *Rhus glabra* , a. Habit, b. Flowers; b'. detail of flower showing disk within stamens, c. Fruit, d. Seeds. Drawn by Regina O. Hughes. From Reed 1971.

*minbdi-hi* (*hi*, plant, Omaha-Ponca); *mon'-bi-dse* (Osage)

*nuppikt* (sour top, Pawnee)

*otgòto* (Onondaga)

smooth sumac (eastern United States)

*tangomóckonomindge* (little dye-bearing tree, Carolina Algonquin, North Carolina)

***tvwv-łakko*** [*tvwv-rakko*] (*tvwv*, sumac,  
***łakko***, big, Muskogee); *tabó:so* (Koasati); *tabosso*  
 (Alabama; see also *Phytolacca*)

On their arrival in the New World, Europeans were pleased and surprised to see sumac. They already knew *Rhus coriaria* of the Mediterranean, which had long been used for dyeing and tanning (Standley 1920–1926). They found Americans using the several native species in many of the same ways they knew. All of the southeastern tribes used the genus in myriad applications (Hedrick 1919, Yanovsky 1936, Moerman 1998).

The most widespread species in Florida is *R. copallina*. Among the Cherokee, the berries were eaten to stop vomiting and bed-wetting; an infusion of bark was poured over sunburn blisters and drunk to increase milk flow (Hamel and Chiltoskey 1975). The Choctaw used an infusion of its roots as a remedy for sore mouth (Bushnell, 1909, Swanton 1946). The Creeks used a decoction of the root to treat dysentery (Swanton 1928a). The Koasati made a decoction of leaves as a bath and gave it to babies to make them learn to walk (Taylor 1940). Sturtevant (1955) was told that the Seminoles used *tvwv* as a diuretic and for “Cow Creek Sickness.” Snow and Stans (2001) recorded that the Seminoles collect and wash roots, peel off the skin, and put them in water. The decoction is used to induce vomiting in people being treated for alcoholism or to make widows throw up to remove the breath of their deceased spouses. *Tvwv* also was mixed with bay (*Persea*) and button snakeroot (*Eryngium*) as part of treatment for people who lose their wives or husbands. Bennett (1997) was told that the fruits were placed in cheesecloth, then steeped in water to make a tea. For emesis much as in Snow’s preparation, a remedy is used for cleansing the body of “pollution” of any kind, including spirits and food poisoning.

In South Carolina’s low country, a leaf decoction is used to bathe “painful places.” The root is peeled and chewed as a remedy for diarrhea and dysentery. Medicines from the plant also are employed to treat leukorrhea, gonorrhea, and bladder trouble (Morton 1974). Murphee (1965) found that people in the Panhandle made a tea of the roots, mixed with cornmeal, to treat erysipilis and other skin problems.

Both *R. aromatica* and *R. glabra* have more restricted ranges in Florida, as they are more temperate. Natchez made a poultice of the roots of *R. aromatica* to treat boils (Swanton 1928a). Ojibwa used the roots in a medicine to treat diarrhea and the bark and berries in a medicinal ceremony (Moerman 1998).

There are records of more people using *R. glabra*, including the Apache, Catawba, Cherokee, Comanche, Creek, Dakota, Flathead, Gosiute, Iroquois, Kiowa, Kutenai, Lakota, Meskwaki, Micmac, Natchez, Ojibwa, Okanagan-Coville, Omaha, Osage, Pawnee, Ponca, Potawatomi, Sanpoil, Tewa, Thompson, and Winnebago (Hunter [1823]

1973, Smith 1933, Vogel 1970, Moerman 1998). Probably the most widespread use was mixing the leaves with tobacco for smoking. Dyes were also widely made (Cannon and Cannon 2003). Gilmore (1931) found empty inflorescences at the Ozark Bluff-Dweller site in Arkansas, and speculated that the fruits were used “as they were by Indians of historic times, in dyeing processes, or medicinally.”

The Cherokee ate the berries to halt vomiting and bed-wetting, and they poured an infusion over sunburn blisters and other burns (Hamel and Chiltoskey 1975). The Creeks used a decoction of the roots to stop dysentery (Swanton 1928a).

### *Ribes*

(Alphonse de Candolle thought *Ribes* was from the old Danish colloquial *ribs*, for *R. rubrum*, the red currant; others, including Leonard Fuchs in 1542, said that *ribes* was a name used by Moors and pharmacists; it may be from Arabic *ribas*, acid tasting, alluding to the fruit)

*aelbesien* (*besien*, possessing; in use for *R. rubrum* by 1549, Dutch)

*casis* [*cassis*] (French, Spanish; perhaps because liquors were made from the fruits of *R. nigrum* in the community of Cassis, near Marseille, France; see de Candolle 1886)

currant (a corruption of Greek *Korinthos*, Corinth, an ancient Greek city; that city also gave English “Raisins of Corinth,” a small variety of grape)

*gadellier* (the plant, probably from Gaelic *gardis*, sour, Quebec)

gooseberry (having nothing to do with the bird called a “goose,” but rather a corruption of the French *grosielle* or *grosell*, words that may have come from Latin *grossulus*, an unripe fig; used in English by 1532 when “Gose berries” were equated with “*grosielles*”)

*gròsaid* (Gaelic, for *R. grossularia*); *groeselier* (the plant, in use for *R. uva-crispa* by 1550; *groselier*, by 1575; French); *groseilles* (the fruit, French; according to some, from Latin *grossulus*; an alternate explanation is that it came from Middle Dutch *croesel*, from *kroes*, crinkled); *groseillier* (the plant, Quebec); *groselha* (the fruit, Portuguese; from German *Kräuselbeere* through French *groseille*; cf. Ferreira de Holanda ca. 1978); *groselheira* (the plant, Portuguese); *grosella* (the fruit, Spanish; from Latin *grossulus*; see Garcia-Pelayo y Gross 1980); *grosellero* (the plant, Spanish)

*hiyo-lókcɪ* (*hiyón*, thus, after this manner, *lókcɪ*, acorn, Muskogee)

*Johannisbeere* [*Johannes beer*] (John’s berry, for *R. rubrum*; rendered *Johans beerlin* in 1542, German)

*Krauselbeere* (first given by Fuchs in 1542 as *Krüselbeer* for *R. uva-crispa*; from *kroes*, crinkled, plus *Beere*, berry, German)

*pe’-çi* [*pe’-çi-ga*] (Omaha)

*raosar* (Gaelic)

ribes (for *R. rubrum*, in use by 1568, English); *ribes* (for *R. rubrum*, Fuchs 1542, Arabic; in French by 1550; in Italian by 1551; in Spanish by 1557); *ribs* (Danish); *rips* (Norwegian); *risp* [*resp*] (Swedish)

*stekelbesien* (*stekel*, stickers, *besien*, possessing; in use for *R. uva-crispa* by 1549, Dutch); thorn grape (used by Henry Lyte in his 1578 translation of Dodoens's *Cruydeboek*); *uva spina* (modern Italian; see Ragazzini and Biagi 1986)

*uva crispa* (in use for *R. uva-crispa* by 1551, Italian)

***Ribes echinellum*** (little hedgehog, a reference to prickly fruits)

[Florida, Miccosukee] gooseberry

*Ribes* was unknown to the Greeks and Romans, or at least it is not mentioned in their literature (de Candolle 1886). Gerarde ([1597] 1975) said the fruits were available in London markets, but were not cultivated (de Candolle 1886, Hedrick 1919). Although Hedrick (1919) said that neither plants nor fruits had a name in Gerarde's time, there are literary records from 1532 equating "Gose berrys" with "*grosielles*." De Candolle (1886) was convinced that the plants were foreign to the Mediterranean, and recorded that *R. rubrum* was still known as *groseillier d'outremer* (foreign current) in France. Similarly, in Geneva, they were *raisin de mare* (sea grape), and in the canton of Soleure *meertrübli* (*meer*, sea, *trübli*, grape).

De Candolle (1886) thought that the French and Breton names indicated cultivation of *R. rubrum* in western France before the Norman conquest. He thought that all the names in use were derived from Gaelic, suggesting *gardis* (sour) as their common ancestor. The examples he gave are *gardes* (in Rouen), *grades* (in Caen), *gradilles* (in Lower Normandy), and *castilles* (in Anjou). Dwelly (1933) confirmed the Gaelic word, although spelled *garg* or *gairge*, as tart or acrid.

Leonard Fuchs published one of the earliest herbals of the 16th century in 1542 (Meyer et al. 1999). He listed what are now the two European species, *R. rubrum* and *R. uva-crispa*. According to Fuchs, *R. rubrum* was cultivated in German gardens, although native in western Europe. He remarked under the "Properties from the Moors" (*Vires ex Mauritanis*): "The berries with their tart taste are pleasing. They cool an upset stomach, slake the thirst that torments both the feverish and others. They dispel aversion to food and arouse the appetite. They check foul effluvia of the belly caused by bile. They remove the gnawing and twitching. They soothe the heating of the blood, and tame the bitterness of bile. The Capuans [from Capua in Italy] preserve the juice of its fruit for year-round use, calling it *Rob de Ribe* [Essence of Currant]." That information agrees with the names in other herbals of the 16th century (Meyer et al. 1999).

Currants were well known in northern Europe at the time the New World was discovered. They were, however, still poorly known in the Mediterranean (de Candolle 1886). *Ribes* is a genus of 150 species growing in the temperate regions of the Northern Hemisphere and the Andes of South America (Fernald 1950, Diggs et al. 1999). There are 9 species in Europe (Mabberley 1997) and 57 (2 of hybrid origin) in North America (Kartesz 1994).

Probably the first record of *Ribes* in the New World was made by Capt. John Smith in 1609, who spoke of them in New England (Hedrick 1919). The species he found there

was *R. oxyacanthoides*. In 1621, Edward Winslow mentioned the same species in Massachusetts. When Linnaeus ([1753] 1957) named this species, he had studied living plants at the *Hortus Upsaliensis* and specimens in the herbaria of Leonard Plukenet and Jan Dillenius. He knew only one other American species, *R. cynosbati*.

Florida has the single species, *R. echinellum*, and it is rare in Gadsden and Jefferson Counties in the Panhandle (Wunderlin 1998). The species was not even discovered until 1924, when it was described by F.W. Coville (1867–1937). In Florida, the plants grow in the region formerly occupied by the Muskogean-speaking Chatot (including the Apalachicola), who later merged with the Choctaws. After the Chatot migrated west into French territory (Swanton 1946), the ancestors of the Miccosukees settled there and nearby at Oscilla River and Tallahassee after 1818 (Williams [1837] 1962). Their principal village between about 1818 and 1836 was on the shores of the lake now called Miccosukee (Simpson 1956). The only other known population for the plants is in McCormick County, South Carolina (Radford et al. 1968, Kral 1983b, Catling et al. 1998).

*Ribes echinellum* is so rare that it is endangered in Florida and nationally threatened (Coile 2000). That rarity precludes much human use, and it is little wonder that there are few records of them. Still, fruits of many species of *Ribes* are eaten. Hocking (1997) wrote that *Ribes* fruits are small and sour, but are used in jellies, preserves, jams, pies, and juices. Most fruits are good sources of vitamin C. He made no mention of *R. echinellum*, but listed 23 others. Earlier, Hedrick (1919) had listed 24 species. Individual plants of *Ribes* vary in taste, and there are also differences in people's preferences (Hedrick 1919). It seems likely that most, if not all, species of the genus produce edible fruits.

Hocking (1997) wrote only that some species are used as brown dyes. Polunin (1969) indicated that, in Europe, leaves of both *R. rubrum* and *R. nigrum* yield a yellow dye. Their fruits provide black (*R. rubrum*) and blue or violet (*R. nigrum*) colors. No information is given by Moerman (1998), Tull (1999), or Cannon and Cannon (2003) on people using *Ribes* for dyeing.

Currants are well known for a number of chemicals that exhibit antibacterial (embelin), antioxidant, and antiviral activity (Moyer et al. 2002, Chitra et al. 2003, Vecera et al. 2003, Knox 2003). *Ribes* species also contain anthocyanins, phenolics, quercetin, and a variety of other compounds (Maatta et al. 2001, Frank et al. 2002, Erlund et al. 2003). Some Asian species are even considered an oral contraceptive for females (Shah 1971, Prakash 1985, Sharma et al. 2001). Most of the chemical analyses and bioactivity studies have been done on *R. nigrum*, but perhaps some of the other species have the same traits.

### ***Rivina*: Rouge-Plant**

(Named for Augustus Quirinus Rivinus [Bachman], 1652–1723, a German physician in Leipzig)

Along the southeastern coast of peninsular Florida are still remnants of the formerly almost continuous tropical forests. Walk into one that has a mature canopy, and you will

feel like you are in a cathedral. The trunks of the trees are widely spaced like columns, and they support the ceiling of the tree crowns, like a mural in the Vatican.

Your first impression will be that there are no understory herbs. Then, when you look more closely, you will find one single herbaceous species scattered about. That is rouge-plant (Florida to Arizona), *Rivina humilis*. This relative of pokeberry (*Phytolacca*) is the only one that grows in the low light of the tropical forest floors. Oddly enough, it also grows in sunny places. There are many odd things about these plants.

On many occasions, I have had students bring in these herbs and complain that they could not figure out what they were. According to them, none of the keys works, or they end up in the Solanaceae, and not the correct Phytolaccaceae. I pointed out to them that they are not alone in their confusion. Common names for the herbs include baby-peppers (Florida), *chile* (*Capsicum*), *chile de ratón* (rat's pepper), jumbee pepper bush (Virgin Islands), pepper bush, *tomatillo* (little tomato, Belize), and wild tomato. Those names came about because of the small, red berries that resemble chiles and tomatoes.

Indeed, most of the names given these plants in the Americas refer to the color of the fruits, or the berries themselves. Some people compare the fruits to seeds of *Bixa orellana* (also called *achiote*, *annato*, *roucou*, *urucu*), that famous tropical American substitute for the Old World saffron (*Crocus sativus*). Those names include *achiotillo* (little achiote, Honduras), rougeplant (Arizona, Texas), and *kuxubcan* [*coxubcan*, *cusucan*, *cuxuban*] (*ku'xub*, achiote, *kan*, snake, Maya, Yucatan, Belize). Others think they are more like blood and say bloodberry (Jamaica, Cayman Islands, Barbados, Trinidad), cat's blood (Puerto Rico, Virgin Islands, Barbados), dog blood (British Antilles), dogberry (Jamaica), and *sangre de toro* (bull blood, Argentina, Uruguay).

To many, the fruits are just red, but they are inventive about saying that. Names meaning red include *carmin* (Costa Rica, Puerto Rico, Colombia), *coral* (Mexico), *coralillo* (Durango, Nicaragua, Belize), *coralillo carmin* (Nicaragua), *coralillo cimarrón* (Sonora), *coralito* (Texas, Durango, Cuba), and wild ruby. More imaginative allusions to the color are *arrebol* [*arrevol*] (red color of the sky, Puerto Rico), *cochinillo* (little cochineal, a cactus-feeding insect, *Dactylopius coccus*), and apparently to a blush in the face of a *demoiselle* (young lady, French Antilles). Indications that fruit was used as dye or ink are reflected in *pinta-pinta* (paint-paint, Colombia) and *saca-tinta* (ink maker, Nicaragua).

Huastec names are *taa t'ele* (baby excrement, San Luis Potosí), *tsakam taa' t'ele'* (little baby excrement, San Luis Potosí), and *akan t'ele'* (baby foot, San Luis Potosí). Those sound distressingly like a major digestive problem in the child. Because diarrhea has been perhaps the most common killer of infants throughout history the Huastec names allude to the use of these plants to treat that malady (Alcorn 1984). In the Virgin Islands and elsewhere diarrhea is one of the

***Rivina humilis*.** Drawn by  
P.N.Honychurch.

prime sicknesses treated with *Rivina* (Petersen 1974, Ayensu 1981, Morton 1981). From the Virgin Islands to Curaçao, a “tea” is made of the entire plant to cure that malady.

Several of the names for the fruit include allusions to colors and medicinal uses and mention that birds feed on them. These are *bonbon codine* (codine candy, Haiti), *bonbon coq d’Inde* (rooster candy, Haiti), *coqueta* (flirt, Belize), fowl berry (Cayman Islands), *hierbe à charpentier* (woodpecker [carpenter’s] herb, French Antilles), *hierba de los carpinteros* [*yerba de los carpinteros*] (woodpecker [carpenter’s] herb, El Salvador), *hierba* [*herba*, *yierba*] *mora* (blackberry herb, Nicaragua), *mata gallina* (chicken killer, Dominican Republic), *ojo de ratón* (rat’s eye, Cuba), and pigeonberry (Arizona, Texas, Sonora). A large variety of birds eat the fruits with impunity. Among the birds feeding on the berries in Florida and Texas are turkeys (*Meleagris gallopavo*), chachalacas (*Ortalis vetula*), mourning doves (*Zenaida macroura*), white-winged doves (*Zenaida asiatica*), mockingbirds (*Mimus polyglottos*), catbirds (*Dumetella carolinensis*), and robins (*Turdus migratorius*) (Texas A&M 2000).

It is not unusual for birds to eat with impunity plant parts that cause problems for humans. There is even disagreement on whether or not the fruits of these plants are edible. Standley (1920–1926) considered them edible, but Nellis (1997) disagreed. That same difference was the norm in my childhood regarding fruits of *Phytolacca*. We were admonished by adults, and by books we found in the library, that the berries were poisonous. One of my friends delighted in eating handfuls of pokeberries to “prove” that

they were harmless. No one at the time ever considered quantity eaten, or variable sensitivity of individuals. Certainly none of us had ever heard of phytolaccatoxin, which is now known to be in *Phytolacca* (Lewis and Elvin-Lewis 1977). Worse, during that time no one even knew of mitogens in the plants and their insidious risks to health when absorbed through skin abrasions.

According to Nellis (1997), consumption of *Rivina* fruits causes numbness of the mouth within 2 hours, with a feeling of warmth in the throat and stomach. Those symptoms are followed by coughing, thirst, tiredness with yawning, vomiting, and diarrhea, sometimes bloody. Leaves and roots contain more toxins, and cattle eating them yield tainted milk, and stools that smell of *Rivina* (Burkill 1966).

The responsible toxins in *Rivina* have not been identified, but they may be similar to those in *Phytolacca* (Nellis 1997). It should be noted that *Rivina* possibly contains mitogens, but there is evidence that they are useful against microbes (Salvat et al. 2001). However, their effectiveness against bacteria is slight and use should be mediated by awareness of their potential dangers.

Surely Linnaeus did not know the poisonous nature of the herbs when he named them for Rivinus. On the other hand, perhaps he did. He was not above naming plants to insult as well as to compliment (Austin 1993). However, this time he seems to have simply been following the suggestion of Charles Plumier who called these plants *Rivina* before him.

Names that are surely references to poisoning or use as medicines are also common, probably because remedies for several maladies include these plants. *Rivina* has been put in medicines to treat colds, diarrhea, difficult urination, flatulence, gonorrhea, jaundice, and ovarian pain. The herbs treat *susto* (fright) in Puebla and Veracruz, Mexico and among the Huastecs of San Luis Potosí (Alcorn 1984, Vásquez and Jácome 1997). Names noting those applications probably include *fleda* bush (British Antilles), *hierbe blanche* (Guadeloupe, Dominique), *liane blanche* (Guadeloupe, Dominique), *quileto blanco* (white quelite), *flor blanca* (white flower, El Salvador), and *skwam butz snya* (*skwam*, herb, Zapotec, Oaxaca).

The name *yerba de cancer* (cancer herb) should not be interpreted literally as malignant tumors. In much of Spanish America, the word “cancer” simply means a dermal sore. Standley (1920–1926), Liogier (1974), and Morton (1981) are among those recording that the leaves are used to treat wounds, sores, and other problems that might be called *cancer* in Spanish.

Other names compare these plants with different species, usually those that are also medicinal. How any of these came to be compared to caimans (from Carib *cayman*, in use by 1577; including the genera *Caiman*, *Melanosuchus*, and *Paleosuchus*), the alligator relatives, is not clear. Still, plants are *caimancillo* (little caíman, Dominican Republic), *caimoni* (usually applied to *Wallenia laurifolia*, Myrsinaceae, Hispaniola), and *caimoni cimarrón* (wild *caimoni*, Hispaniola). Two other names that are comparisons to famous medicines are *hierba del zorrillo* (skunk herb, name also applied to *Petiveria alliacea*, Mexico) and *stack-mahack* [*stakamahatchi*, *stock ma hork*, *stopmahatje*] (possibly from *takahamaca*, a name for *Bursera*, Virgin Islands).

There are no obvious meanings for *kahold* (West Indies), *penzon mazoumba* (Haiti), *pimpín* (Colombia), *teyweso* (Guarijío, Sonora), and *ucusuiro* (Sonora). However, *laman la yé* (it cries for thee, Haiti), *maman la cri* (mama it cries, Haiti), and *bacot mítica*

(snake's pillow, Mayo, Sonora) are ominous. In spite of these names, some tout the herbs as good goat fodder (Yetman and Van Devender 2001). Maybe the goat's reputation for being able to eat anything with impunity is its salvation.

These plants have a surprising tolerance for temperatures and moisture variations. The herbs grow from Florida to Texas, Arizona and Oklahoma, south through Mexico, the Bahamas, West Indies, and Mesoamerica to Peru and Argentina. It is almost incomprehensible that plants growing in the shade of a tropical West Indian forest can also grow in the desert canyons of Arizona and Mexico. Yet, when the rains are ample in the Sonoran and Chihuahuan Deserts, the herbs appear.

This *Solanum* look-alike is a monotypic genus, with the only species scattered through the Americas (Rogers 1985). The flowers are not particularly attractive to most people, but *Rivina* most likely has been brought into cultivation for its bright fruits. Maybe, like *Phytolacca*, it too will amaze those who examine its chemistry. Already, *Rivina* has surprised those who have examined the phylogeny of the family. Most recent data suggest that the family is polyphyletic, and strongly linked with Nyctaginaceae (Downie and Palmer 1994). Can this really be a highly modified *Bougainvillea*? Or, is *Bougainvillea* actually a drastically modified *Rivina*?

### ***Rosa***

(The ancient Latin name; related to Greek *rhodon*, Akkadian *russu*, red)

*bakó paká:li* (*bakó*, briar, *paká:li*, flower, Koasati)

*goláp* (Bengali); *gul [guli]* (Persian, Punjabi, Afghanis tani); *guláb* (Hindi)

*roas* (Frisian); *rodea [rhodon]* (Greek); *roos* (Dutch); *ròs* (Gaelic); *rós* (Icelandic); *ros* (Swedish); *rosa* (Italian, Spanish, Portuguese); *rósa* (Old Norse); *rose* (Danish, French); *Rose* (German)

rose-hips [heps, hepps] (from Old English *héope*, related to Old Saxon *hiope*, Middle High German *hiefe*, Old Teutonic *heupón*, a thorn bush; equated to *Rosa canina* with "hip-bramble" in A.D. 1386)

*vered* (Hebrew)

***Rosa Carolina*** (from Carolina)

*a'kiska* (Ofo)

***Rosa Carolina.*** From Britton and Brown 1897.

Carolina [dog] rose

*kati ancho* (*kati*, thorn, *ancho*, mantle, Choctaw)

pasture rose

*pussaqweinbun* (Strachey said in [1612] 1953 that this Virginia Powhatan word meant a rose)

*tsist-uni'gisti* (rabbit food, Cherokee)

***Rosa palustris*** (of marshes)

*hvyo palecv* [*hiyópalécv*] (*hvyo*, harvest, *palecv*, ten year, Muskogee)  
swamp rose

Surely, the oldest use of roses is their edible fruits, called “hips” in English. Rose seeds have been found dated at 5000 B.P. in the Netherlands and at 3500 B.R in England (Widrechner 1980). In Britain, rose-hip seeds were found with the skeleton of a Neolithic woman from 2000 B.C. (Genders 1988). The discovery of that antiquity is one indication of the widespread and ancient use of this food. Hips are rich in vitamin C and contain malic acid. Malic acid is one compound that prevents gout, the excess accumulation of uric acid, so the tasty food is also medicine (Genders 1988).

Theophrastus, 372–287 B.C., distinguished between wild roses as *cynosbaton* (dog rose) and cultivated types he called *rhodon* (rose) (Widrechner 1980). Pliny, A.D. 23–79, recorded one of the oldest stories for Eurasian roses, although there are even older tales related to Greek deities. He wrote that the Greeks called the plant *cynorrhodon* (*cyno*, dog, *rhodon*, rose), because a woman had a dream that it would cure the bite of the mad dog. She sent some to her son who was in the military and who had been bitten by a dog. Pliny wrote that the son was beginning to show a horror of water, “when a letter arrived from his mother, begging him to obey the heavenly warning. So his life was unexpectedly saved.” The plants are still called dog rose, but Linnaeus put that name in Latin as *Rosa canina*.

An even older history regarding roses is known from the Middle East and India. Roses were grown in the physic gardens of western Asia and northeastern Africa 5000 years ago (Lehner and Lehner 1960, Simpson and Conner-Ogorzaly 1995). Roses are associated with many religious leaders, including Brahma, Buddha, Confucius, Jesus, Mohammed, Vishnu, and Zoroaster (Swerdlow 2000).

“Attar,” the oil of the damask rose (*R. ×damascana*), Rosaceum, an ointment of rose oil and honey, and rosewater were the most lavishly used perfumes and cosmetics in Persia, Egypt, Greece, and Rome (Lehner and Lehner 1960). Being scented with attar is still the sign of devout Muslims and Hindus. However, use of rose oil is not confined to those religions. Rose oil is a worldwide component in 46% of men’s perfumes and 98% of women’s fragrances (Lawless 1995). Among the more than 300 components identified in rose oil are citronellel, farnesol, geraniol, nerol, phenyl ethanol, and stearopten (Lawless 1995).

According to an Indian story, rosewater was discovered in 1612 by Nur-i-Jehan Begun, on the occasion of her marriage to the emperor Jehangir. While they were walking in his palace gardens along the canals and fountains decked with rose petals in celebration of their wedding, she noticed an oily film on the water surface produced by the action of the sun on the rose petals. Fascinated by the heavy scent of this oil, she ordered it bottled for later use. It was named *Atar-Jehanghiri*, perfume of Jehangir. This *attar* (fragrance, *atir*, Persian, ’itr, Arabic, *itr*, Hindi) was considered the most precious of all perfumes (Watt [1889] 1972). Sometimes it is still called by its full name in English and Persian, *atar-gul* (rose-perfume).

Europeans were fascinated with roses when the New World was discovered and imported them for both beauty and utility. The newcomers also found several species native to the eastern United States. The indigenous tribes did not share the Old World fascination with them, but several species were used (Gilmore 1919, Moerman 1998). The Cree and Iroquois used *R. acicularis* in food and medicine, particularly for treating coughs and sore eyes. The Ojibwa and Omaha used *R. arkansana* similarly. They also used it to heal wounds and as a tonic (Kindscher 1992). Both the Cherokee and Ojibwa used *R. virginiana* to expel intestinal worms from children, to treat sore eyes, and to heal wounds.

Records have been found for use of both native species in Florida. The Menomini ate the fruit skin of *R. Carolina* for stomach trouble (Moerman 1998). The Cherokee used an infusion of bark and roots of *R. palustris* to treat intestinal worms, and a decoction of roots to stop dysentery (Hamel and Chiltoskey 1975).

In spite of their names, the Chickasaw rose (*R. bracteata*) and Cherokee rose (*R. laevigata*) are not native species used by those tribes. These plants were imported from China and naturalized (Wunderlin 1998). The Chickasaw rose was imported in 1870, and it is now a pest in Louisiana, Mississippi, and Alabama (Hocking 1997). The Cherokee rose has a similar history, and it is a pest in the southern United States (Hocking 1997). So, a rose by any other name may smell as sweet, but it will smother more desirable natives in doing so.

***Roystonea***

(Orator Fuller Cook, 1867–1949, named the palm after General Roy Stone, 1836–1905, an American Army engineer in Puerto Rico)

***Roystonea regia*** (royal)

*ara'uwa* (Carib, Suriname)

*hiskiwisá:ki* [*hiskiwisá:hí*] (*hiski*, leaves, *wisá:ki*, pointing-outward, Mikasuki)

*jagua* [*yagua*] (royal palm leaf, Taino, Mexico); *palma de yagua* [*cubana*] ([Cuban] palm giving leaves, Puerto Rico)

Konnings palm (Antilles)

*manaca* (Taino, Greater Antilles)

*palma* (palm, Dominican Republic); *palma cana* [*criolla*] (cane [Creole] palm, Cuba); *palma real* [*cubana*] ([Cuban] royal palm, Dominican Republic, Puerto Rico, Belize, Guatemala, Mexico); *palmiste* (palm, Haiti)

[Cuban] royal palm (Florida, Bahamas, Puerto Rico, Belize)

*waa* (Cuna)

Coll y Toste (1972) said that the first record of *Roystonea* came from Oviedo in the 1500s. Oviedo wrote, “*Entre las otras palmas hay un gnero dellas, que los indios llaman manaca*” (Among the other palms there is a genus of them that the Indians call *manaca*). That Taino name is no longer used for the royal palm, but it is used for *Calyptronoma* and *Prestoea* (Scott Zona, personal communication 2003). However, the Taino term *yagua* remains in common names for *Roystonea* and shows the importance of the fronds in thatching *bohios* (houses) of the *campesinos* (Coll y Toste 1972).

Europeans soon learned the utility of these large trees. The fruits were especially good for feeding swine (Austin 1980). Spanish ships leaving Cuba often were

***Roystonea regia*.** From Little and Wadsworth 1974.

provided with not only pigs but also a store of royal palm fruits to feed them (Millspaugh 1907). When the Seminoles moved into Florida, they became particularly fond of pigs. Indeed, one translation of their tribal name Miccosukee is chief (*micco*) pig (*sukee*). The Gainesville area was a famous village for Seminoles and their fondness for pigs remains in “Hogtown Creek.” Some still irreverently call the city of Gainesville “Hogtown.”

In the 1760s, when William Bartram was traveling in Florida, he found the royal palm in what is now Volusia and Lake Counties. He called the trees *palma elata*, and wrote that they had a “strait trunk...sixty, eighty or ninety feet high, with a beautiful taper of a bright ash colour.” There are no longer royal palms in the area, and Harper (Bartram [1791] 1958) speculated that the freeze of 1835 killed them. Zona (1996) discussed the northern Florida *Roystonea* in more detail.

Given the Seminole fondness for swine and the disjunct location of royal palms found by Bartram, it is tempting to believe that the Miccosukee planted them there. Whether or not that is the case, they still had a name for them when Sturtevant (1955) worked with them.

Cubans make the root into a diuretic medicine, and some think it good for diabetes, perhaps because it is emollient (Roig 1945). As with most palms, the terminal bud is edible, but harvesting kills the tree (Morton 1968b). The fruit pulp is also edible, as the Spanish and Miccosukee learned long ago.

## *Rubus*

(Ancient Latin name of the blackberry)

*baer* (berry, Norwegian)

*bakcó* (Koasati); *bakhe* (Mikasuki); *bissa* (Choc taw); *bissa'* (Chickasaw); *kvco* (Muskogee)

blackberry (a name first applied to *Rubus fruticosus* in Europe about A.D. 1000; subsequently applied to all members of *Rubus*)

bramble (from Middle English *brambel* or *braembel*, first used in English about A.D. 1000); *braam* (Dutch); *Brombeere* (bramble berry, German)

cloudberry (originally applied to *Rubus chamaemorus* in Europe by at least the time of John Gerarde's *Herball* in 1597; the species name means "ground-berry," and the origin of "cloud" in the name is unknown)

*co'kake'ñic* (Atakapa)

dewberry (a berry with dew-drops on it; originally applied to *Rubus caesius* of Europe by the time of the English translation of Rembert Dodoens's book on herbs in 1578, and later applied to *R. canadensis* and other American species)

[*fir, feir*] *dhريس* [*dreas*] (*fir*, chief, *dhريس*, briar or bramble, Gaelic)

*iya'fhu* (maybe *iya*, raccoon, *i'fhu*, seed, Ofu)

*kanugu'la* [*kanugahli*, *kah noo gah hlee*, *kanugu'la*, *ka-nu'-ga-tli'*] (scratcher, Cherokee; there was a place called *Kanu'gulayi*, or *Kanu'gulun'yi*, "Brier place," a Cherokee settlement formerly on the Nantahala River, about the mouth of Briertown Creek, in Macon County, North Carolina)

*kuskite'mina* (Plains Cree)

*mehowimi* [*mehowiminac*, *m'howiminac*] (Delaware)

*nzúkii-lehlookihldashak* (from *nzúkeew*, black, *lehlookihlaash*, raspberry, Ontario Delaware, O'Meara 1996)

raspberry ("rasp" is of unknown etymology, but appears to be related to "raspis," from 1532, which was perhaps derived from Old French *raspeit* or *raspise*, and Italian *raspato*, a rose-colored wine, ultimately from Medieval Latin *raspatum* or *raspa*, a bunch of grapes. From ca. 1460 this was interpreted as being a wine made from raspberries. William Turner's *Names of Herbes* published in 1548 stated, "*Rubus ideus* [*sic*] is called...in englishe raspeses or hyndberies." John Parkinson also mentioned "raspis" in *Paradisus Terrestris* in 1629. Strachey 1612 wrote of "raspices." However, by 1623 Europeans had begun applying "raspberry" to fruits of *Rubus idaeus*, and that trend continued with the eventual disappearance of "raspis.")

*ronce* (French); *rovo* (Italian)

**Rubus.** *Rubus cuneifolius* . *Rubus trivialis* . Both from Britton and Brown 1897.

*sájis óchia* (*óchia*, berry, Onondaga)  
*silva* (forest, from Latin, Portuguese)  
*smeur* (blackberry; also means anoint or smear, presumably because it was used for dye, Gaelic)  
 thimble-berry (applied to the black raspberry by Thoreau in *Walden*, from 1854)  
*udlosinvda* (Cherokee)  
*wa-çki'-the ça-be* (*wa-çki'-the*, fruit, *ça-be*, black, Osage)  
*wi-ya'ro* (blackberry, Catawba)  
*zarza* (Spanish)

**Rubus argutus** (leaves sharply toothed or serrated)

**okwoŋi** (Koasati)

saw-tooth blackberry [sawtooth blackberry]

**Rubus cuneifolius** (cuneate-leaved)

*bakŋsalâ:lî* [*bakhe shaalale*] (twining briar, Mikasuki)

brier-berry

*kacohalkoci* [*kv'co-hv'lkv*, *kv'co-palv'knv*] (*kvco*, briar, *hvlkvte*,

climbing, Creek, Muskogee); *kvco* **hueŋv** [*huerv*] (*kvco*, briar,

*huetv*,

standing, Muskogee); *kvco-em-ette* (*ko'co*, briar, *emetv*, it gives [fruits], Muskogee)  
knee-high [sand] blackberry

***Rubus flagellaris*** (like a whiplash, alluding to the branches)

bumble-kites [bumblekites] (so called because "children eat so many that their kites or bellies rumble," according to Young 1945 in Coffey 1993)

cloudberry-root

finger-berry (New York)

northern dew-berry

*ronce à flagelles* (whip bramble, Quebec)

running blackberry

sow-teat [blackberry] (Connecticut, New Hampshire)

thimble-berry (Michigan, New York)

*u-dlo'-si-nv-da* (dewberry or boysenberry, Cherokee)

***Rubus trivialis*** (ordinary)

*biuntalali* [*bissuntalali*] (*bissa'*, blackberry, *talaalih*, spreading, Choctaw)

blackberry

*haiyantalali* [*aiuntalali*] (perhaps *hayyi* [*hayyon*] is archaic for plant or vine, but is no longer used, *okpolo*, bad, Choctaw; Byington glossed *haiyunkpolo* as "weed")

*iuntalali* (from *talaalih*, to spread out, so "spreading vine," Choctaw)

southern dewberry

*Rubus* comprises 250 species, plus numerous apomictic lines (Mabberley 1997). European use of *Rubus* as food and medicine dates from at least as early as the Romans and Greeks, probably much earlier.

Hogan (1978) found pollen of *Rubus* at the Fort Center Glades village on Lake Okeechobee. Presumably, they were using the plants as have people throughout the range of the genus. It is known that the Timucua also used blackberries (Hann 1986). Fruits of all species were eaten as food (Hedrick 1919, Yanovsky 1936, Moerman 1998), and at least the Choctaw, Creek, Koasati, and Yuchi recognized a "blackberry month."

The Cherokee used *R. argutus*, *R. flagellaris*, and *R. trivialis* in an infusion of roots or leaves for diarrhea, rheumatism, as a diuretic, for venereal disease, and as a hemorrhoid remedy (Hamel and Chiltoskey 1975). They also chewed the root to cure a coated tongue. The Catawbas used *Rubus* to treat diarrhea (Speck 1937, 1944). The Alabamas used *Rubus* for a toothache remedy and in a poultice against pneumonia (Taylor 1940).

Small (1933) found the Seminoles using *R. trivialis* to treat stomachache. Sturtevant (1955) found the Miccosukee using *bakcsalâ:lî* in a mixture for chronic sickness, in birth ceremonies, and for food. Modern Seminoles on the Big Cypress Reservation eat the fruits and use the plant in medicine. The entire plant is placed in hot water and the

decoction taken orally for “Ant Sickness,” and to treat itchy skin; other plants may be added (Bennett 1997).

***Rudbeckia***

(In using this name, Linnaeus honored his professor Olaus Olai Rudbeck, 1660–1740, physician and professor of anatomy and botany at Uppsala)

***Rudbeckia hirta*** (rough hairy)

*a'wi-akta'* [*a-wi-a-ka-ta*] (deer eye, Cherokee); deer's eye daisy  
black-eyed susan

*ha:sʔâyhi* [haash (th) aime] (haash, sun,  
*ʔâyhi*, shot or shooting, Mikasuki)  
*memakate'nîngwe* (black eyeballs, Potawatomi)  
*paká:lilá:na* (*paká:li*, flower, *lá:na*, black, Koasati)

Linnaeus ([1753] 1957) named the genus and species, and since then, the species found in North America have brought the total to 15 (Mabberley 1997). Gilmore (1931) found some *Rudbeckia* at the Ozark Bluff-Dweller site in Arkansas, but offered no

***Rudbeckia hirta*.** a. Lower part of plant, b. Upper part of plant with flowers, c. Seed. From Buchholtz 1968.

suggestion as to its possible use. Given its popularity with historic tribes, it may have been medicinal.

Most people within the range of this species are recorded as having used it, including the Cherokee, Iroquois, Ojibwa, Potawatomi, Shuswap, and Seminoles. The Cherokee used the herbs to bathe sores, for diarrhea, and to wash snakebites (Hamel and Chiltoskey 1975). Both the Cherokee and Iroquois used it to treat worms (Moerman 1998). Small (1933) recorded that the Seminoles used a cold infusion to treat headache and fever, although Sturtevant (1955) found no common name or use for the plants. Bennett (1997) was told that modern Miccosukee use *haash (th) aime* to treat sunstrokes and headaches.

*ha:słayhi*

That name was given (as ) by Sturtevant's (1955) informants to the "Sun Sickness" itself (see also *Sabatia*).

Leaves contain an oleoresin (Perkins and Payne 1978). Both Turner and Szczawinski (1991) and Mabberley (1997) noted that the plant was "toxic," without further comment.

### *Ruellia*

(Named for the French herbalist Jean Ruelle, 1474–1537)

#### *Ruellia caroliniensis* (of Carolina)

East Tennessee pinkroot ("pinkroot" is a name usually used for *Spigelia*)  
[false, Kentucky, wild] petunia

*Ruellia* is a genus of about 150 species found in the tropics and in temperate North America (Mabberley 1997). When he described it, Linnaeus ([1753] 1957) knew 8 species. Among those he described was *R. tuberosa* of the Caribbean, a plant of considerable medicinal reputation (e.g., Ayensu 1981, Morton 1981). Neither Vogel (1970) nor Moerman (1998) included the genus even though there are about 20 species within the geographic range covered by their research (Kartesz 1994).

Sturtevant (1955) found no Seminoles using the plants, but Hocking (1997) said that *R. caroliniensis* was used by them as an adulterant of pink root (see *Spigelia*). He also recorded that a decoction was used for stomach distress by the Seminoles.

Porcher (1863) included *R. strepens*, with the comment, "The leaves are said to be subacid." Millsbaugh (1892) did not include the genus, nor did Bremness (1994), Bown (1995), or Duke et al. (2002).

### *Rumex*

(Classical Latin name for sorrel, *R. acetosella*; akin to Akkadian *ramaku*, to pour, Hebrew *romak*, spear or javelin)

***Rumex verticillatus*.** From Britton and Brown 1896.

*acederas* [*azederas*] (sorrel, Spanish for *R. acetosa* by 1557); *acetosa* (sorrel, Italian by 1551)

*Ampfer* [*Ampffer*] (dock or sorrel, German for *R. acetosa* by 1545)

bloodwort (because it “cleanseth the blood and strengthens the liver,” Culpeper 1653)

*cañaigre* [*cañaigre*, *cañaigria*] (from *caña*, cane, *agria*, sour; name for *R. hymenosepalus*, but sometimes used generically, Spanish)

dock [docken, singular] (from Old English *docce*, in use by the 1100s; related to Middle Dutch *docke*, Old Danish *adokke*, Old French *éadocce*; Gaelic *dogha*, cognate with English “dock,” but designating “burdock,” *Arctium lappa*)

*geoirean* (bitter or sharp [taste], Gaelic; they also call it *copag*, and *samh* for *R. acetosella*)

*høymole* (*høy*, hay or high, *mole*=?, Norwegian)

*osielle* (sorrel, French for *R. acetosa* by 1550)

*patientie* (for *R. alpinus* by 1549, Dutch)

sorrel (in English for *R. acetosa* by ca. 1400; William Turner in 1568 compared it to *Oxalis*; from the Old French *surele* from the 1100s, which is the diminutive of Germanic *sur*, sour; in modern German *sauer*)

sour-dock (used for *R. acetosa* or *R. acetosella*)

*syre* (sour, Norwegian for *R. acetosa* and allies)

***Rumex verticillatus*** (having flowers in whorls around the stalk)

[swamp, water] dock

*hoshukome* (*hoshuk*, grass, *home*, bitter, Choctaw)

Europeans were already distinguishing between the “docks” and the “sorrels” by the time Old English was spoken in the 1100s. “Dock” typically meant the larger-leaved species

of *Rumex*, with comparatively little sour taste. "Sorrel," on the other hand, meant the smaller-leaved species with a distinctly acid taste to the leaves.

Sorrel has been cultivated in Europe since the Middle Ages. For many years it was believed that the acid in the plants would dissolve the troublesome bones in fish, such as shad. To accomplish that, the English invented "greensauce." The mixture, which was intended to accompany fish and meat, got its name because it was made from sorrel pounded into a paste with vinegar or lemon juice and sugar (Davidson 1999). It did not remove the bones, but it added an interesting taste.

Fernald et al. (1958) said that all of the 15 or so species in the eastern United States could be eaten, but that care must be taken to gather only the young leaves as they become bitter with age. Two advantages to using *Rumex* greens is that they are wholesome, and that they lose little bulk in cooking so that a small bunch makes a larger meal than other greens. The first one or two waters in which they are boiled should be thrown away to remove the strong taste. At least the leaves of *R. crispus* contain abundant vitamin C and more vitamin A than carrots (Tull 1999).

Some Europeans used *Rumex* as food more than others. Culpeper, in 1653, had an explanation for that view and wrote, "Yet such is the nicety of our times (forsooth) that Women will not put it in the Pot because it makes the Pottage black; Pride and Ignorance (a couple of Monsters in the Creation) preferring Nicety before Health" (Fernald et al. 1958).

Soon after they arrived in the New World, Europeans introduced *R. acetosa*, *R. acetosella*, *R. conglomerates*, *R. crispus*, *R. domesticus*, *R. patientia*, *R. pulcher*, *R. obtusifolius*, and *R. maritimus* (Fernald 1950). Within a short while after Europeans arrived with their Old World plants, indigenous Americans adopted those *Rumex* and added them to their foods and medicines. Moerman (1998) lists the Blackfoot, Cherokee, Cheyenne, Cocopa, Costanoan, Dakota, Havasupai, Delaware, Iroquois, Isleta, Kawaiisu, Mendocino, Micmac, Mohave, Mohegan, Montana, Navajo, Ojibwa, Paiute, Pima, Rappahannock, Shoshoni, Thompson, Yavapai, Yuri, and Zuni as using *R. crispus* for food and medicine. The Apalachee used *R. acetosa* in medicine (Hann 1986). That quick incorporation of European species is both a measure of indigenous Americans' adoption of alien plants, and their prior knowledge of native species.

The Cherokee ate *R. acetosa*; they and the Iroquois ate *R. acetosella* and *R. crispus* leaves (Moerman 1998). Fernald et al. (1958) indicated that indigenous tribes ate the seeds of various *Rumex*, and documentation has been found for the Cocopa, Costanoan, Kwasiisu, Mendocino, "Montana Indians," Navajo, Paiute, and Pima (Ebling 1986, Moerman 1998). Eastern tribes most likely also ate the seeds.

Dock leaves are eaten, but they are more famous as medicinal plants. In 1398, a book on medicines stated, "Al manere Dockys heele smyrtynge of Scorpions." Later, they were largely relegated to relieving the itching and burning cause by nettles (*Urtica dioica*). In a related use, Tull (1999) advocated using dock "tea" to treat poison-ivy rash.

Reverend Manasseh Cutler wrote in 1785 that the indigenous tribes around Boston used *R. verticillatus* to clean ulcers that would not otherwise heal (Vogel 1970). The Choctaw tried to ward off smallpox by bathing in a decoction of *R. verticillatus* leaves (Bushnell 1909, Taylor 1940). The Chickasaw used "common dock" as a remedy against jaundice (Swanton 1928b). The Houma used *R. salicifolius* to treat liver trouble,

intestinal disorders, jaundice, and menstrual problems, and probably also used *R. verticillatus* (Speck 1941).

Indeed, indigenous tribes across North America used native and introduced *Rumex* species for a variety of maladies. Many of the uses concentrated on external problems like sores and cuts that needed help healing (Vogel 1970, Moerman 1998). Two alien species were incorporated into the American medicines; *R. obtusifolius* made the U.S. Pharmacopoeia between 1820 and 1905, and *R. crispus* between 1863 and 1905 (Vogel 1970). *Rumex* was first listed for treatment of skin diseases, as alteratives and depuratives, but it later was included among laxatives and tonics. All species are high in tannins and oxalic acid, and these in conjunction with the anthraquinones are among the chemicals responsible for their actions (Fernald et al. 1958, Vogel 1970). Anthraquinones are particularly notable for inhibiting fungi (Foster and Duke 1990). Herbal extracts are mildly antibacterial toward both Gram-positive and Gram-negative bacteria (Duke et al. 2002).

Several of the older references allude to the similarity between *Rumex* and rhubarb (*Rheum × hybridum*), both in the Polygonaceae. Indeed, roots of both genera have long been applied as laxatives (Millspaugh 1893). Among the compounds found in *Rumex* are anthraquinones, particularly emodin and rumicin (Kay 1996). However, it should be noted that while the anthraquinones are laxative, the tannins are antidiarrheal (Foster and Duke 1990, Duke et al. 2002).

Gaelic people obtained a black dye from the roots mixed with copper (Dwelly 1933). Quick adoption of alien *Rumex* as a dye source suggests that other native species were formerly used. Tull (1999) indicated that tans, browns, green, gold, mauve, yellow, and orange can be made from different *Rumex*, and that the Navajo used them for those colors. The Cheyenne obtained a blue dye from some species that was used to color feathers and porcupine quills (Tull 1999); although Moerman (1998) listed only reds and yellows. The Choctaw made a yellow dye from the roots of what Bushnell (1909, 1917) identified as *R. crispus*, but the Houma used the native *R. salicifolius* roots to make a dye for cane and palmetto baskets (Speck 1941).

# S

## *Sabal*

(Michel Adanson used a vernacular American name for the generic name of these palms in 1763; could he have taken it from the Mayan word *sibul*, for a black bird?)

***Sabal etonia*** (named because it grew in the “Eton Scrub” of northern Florida; ultimately, either from *Utina*, the name of a Timucuan people who lived in Putnam County after withdrawing from the Tomoka River, or from Creek *atan*, from, and *aia*, go, or “go elsewhere”)  
scrub palmetto (Florida)

***Sabal minor*** (smaller)

[little] blue stem [bluestem, palm] (Alabama, Texas, Florida)

*latanier* [*latanier*] (Louisiana)

[bush, dwarf, swamp] palmetto [palm] (Texas, Alabama, Florida, Georgia)

*taala* (Alabama)

***Sabal palmetto*** (diminutive of Latin *palma*, the palm tree, probably through Spanish *palmito*)

big top (Bahamas)

[swamp] cabbage [palm, palmetto, tree] (Florida)

*cani* (the leaf, Timucua)

*chaw-fo-ka-naw* (language?, USA)

*guana cana* (*guana* cane; “*guana*” is a Taino name for some tree, perhaps this, Cuba); *guano rabo de cote* (“cote’s” tail cane, Cuba)

*latanier* (*latania* is an indigenous word from Mauritius for a palm there; apparently, this native plant became confused with the one from Africa, Houma, Louisiana)

*maxontkayixki*’ (Biloxi)

*palma [cana]* ([cane] palm, Cuba)

***Sabal*.** *Sabal etonia* . The leaf and fruit cluster are from *S. etonia*. *Sabal palmetto* . Both drawn by P.N.Honychurch.

[bank, Carolina, common, hat] palmetto[-tree] (perhaps first recorded as *palmito* by Barrientos 1567, who noted that Menéndez and his men had to resort to eating them, southeastern United States, Bahamas); *palamito* (Houma, Louisiana)

pond thatch (Bahamas)

*tala* (Choctaw); *tá:la* (Koasati); *taalachoba* (*taala*, palm, *choba*, big,

Alabama); ***ta:laʔákko*** [*ta:larákk*, *talalocho*,

***ʔákko***, *tallaloko*, *talv rakko*] (*talv* or *tala*, palm, big, Creek; maybe first recorded as *talalocho* by Simmons [1822] 1973); *talcó:bí* (*tala*, palm, *có:bí*, big, Mikasuki); *talimushi* (*tala*, palmetto, *imushi*, it's uncle, Choctaw)

[pond-, white-] top (Bahamas)

Of the three species of *Sabal* in Florida, the first discovered by European science was not the most obvious. People from at least the time of Menéndez in the 1560s mentioned cabbage palms (Barrientos 1597), but it was the trunkless *S. minor* that was first described by Jacquin in 1776. It was not long before *S. palmetto* was “discovered,” and it was named by American Thomas Walter in 1788. Both put their species in *Corypha*. The

first Florida palm to be called a *Sabal* was *S. etonia*, described in 1896. People had finally discovered Adanson's *Sabal* and realized that *Corypha* was an Old World genus. *Sabal* now has 15 species (Zona 1990).

Surely the oldest Florida use of *Sabal*, regardless of species, is of the leaves (Austin 1980). Fontaneda ([1575] 1944) recorded palm use by the Calusa. Of the men he wrote that they "*andan en cueros, sino solamente vnos brageros tejidos de palmaque*" (go naked, except only some breech-cloths woven of palm). Women, he wrote, wear "*un mantellin de vnas palmas Rajadas y tejidas*" (a shawl made of a kind of palm-leaf, split and woven). Jonathan Dickinson found the Jaega men wearing the same loincloth in 1699 (Andrews and Andrews 1945). Either of the three *Sabal* could have been used for these clothes, but *S. palmetto* was the most abundant.

It would appear that cabbage palm fibers were more often used within and outside their native range than is at first obvious. Whitford (1941) found that the materials had been traded with northern tribes and appeared among artifacts from the Winnebago of southern Wisconsin and the Iroquois of New York. Those two tribes were 600 to 700 miles north of the closest *S. palmetto* stands. He had identified palmetto fibers in cords used to make carrying straps for bags, although the Iroquois had covered them with softer fibers. The Cherokee were known at the time to make baskets with them (Whitford 1941).

The Timucua used palm leaves for thatch, and there still is a locality in Alachua County called "Kanapaha" (*cani*, palm, *paha*, house), based on their language (Simpson 1956). Leaves are still used for thatching traditional Seminole houses called *cuko* (Creek) or *ciki* (Mikasuki), in a style likely modified from the Glades people before them. In addition, the Seminoles use the leaves to make potato-drying mats, fish drags, and rope (Sturtevant 1955). The Alabama used strips of the leaves to hang meat for smoking (Sylestine et al. 1993). Vignoles ([1823] 1977) wrote of these palms: "There are a number of varieties of the palmetto, from whence the inhabitants and even the Indians form ropes: much of the same tackling of the fishing boats is made of this grass, which is rather the better for being kept wet, as it is apt to crack like rushes when dry: we also find in the country that palmetto, from whence the rigging, cordage and cables of most of the West India small craft are made."

From the trunks of *S. palmetto*, the Seminoles made house poles, food paddles, arrows, hunting dance staffs, heddles, ballsticks, and skin-drying frames (Sturtevant 1955). Wood was used for salt by the same process as potash, burning and using ashes (Morton 1968b).

According to Morton (1968b), one of the ways the Seminoles ate the fruits was to reduce dried fruits to meal, which they made into bread. They also ate raw fruits or made them into syrup.

Sturtevant (1955) recorded that the Seminoles used the plants for "fish poison"; no further details were given. They also mixed the fruits with an unidentified grass to treat "Grass Sickness" (low fever, headache, weight loss) (Sturtevant 1955). Bahamians have a similar use as a cure for fish poisoning by eating the palm heart or steeping it in gin for a medicinal drink (Eldridge 1975).

The best-known modern use of the palms is to cook and eat the terminal bud or "cabbage" (Morton 1968b). Both *S. etonia* and *S. minor* were used similarly (Yanovsky

1936). A lesser-known use was to extract the fresh pith of upper trunk, which was eaten as is or made into “pie.”

The heart has been eaten since about the time of the first Spanish visitors to Florida. The first records known were of the Spanish troops under Pedro Menéndez de Avilés extracting palm hearts on their overland route to expel the French Huguenots at the south end of Anastasia Island (St. Johns County) in 1565 (Barrientos 1567). Apparently, the heart was not eaten before the Europeans brought metal tools into this region because the utensils available to the indigenous people were not adequate to extract the heart efficiently.

### *Sabatia*

(Michel Adanson named this genus for Liberate Sabbati, b. 1714, an Italian surgeon in Rome who published in 1745)

*Sabatia brevifolia*. Drawn by  
P.N.Honychurch.

*Sabatia angularis* (with angles on the stems)  
Bitterwurz (bitter herb, German)  
[bitter-, pink-] bloom [-clover] (West Virginia)

[American, angular, red] centuary [centory, centry] (applied by 1831; “centuary” is the English rendition of *Centaurium*, a related genus described by London apothecary John Hill, 1716–1775)

eyebright (North Carolina; in Europe usually given to *Euphrasia officinalis*)

[square-stemmed] rose gentian (“gentian” is from the genus *Gentiana*, a related bitter medicine)

rose-pink [rosepink] (etymology of “pink” as a plant is obscure, but perhaps from “pink eye,” small eye, related to French *oeillet*, the diminutive of *oeil*, eye, from Medieval Latin *ocellus*; the name “pink” was originally given to *Dianthus*, Caryophyllaceae, in the 1500s; perhaps “rose-pink” simply refers to the color)

square-stemmed sabatia (a book name)

wild-succory (“succory,” used since 1533; a corruption of chicory, *Cichorium*, Asteraceae, another bitter medicine)

***Sabatia bartramii*** (named for the Bartrams, John, 1699–1777, and his son William, 1739–1823)

Bartram’s rose gentian [rosegentian] (a book name)

marsh pink

***Sabatia brevifolia*** (short-leaved)

quinine [flower, herb]

shortleaf rose-gentian [rosegentian]

***Sabatia campanulata*** (bell-shaped)

marsh pink

slender rose-gentian [slender rosegentian]

***Sabatia stellaris*** (starlike)

*kococompahá:ka* (*kocecvmpv*, archaic for star, *vhake*, resembling, Creek); *owa:cikâ:bî* (star replica, Mikasuki)

marsh [sea] pink [sea-pink]

rose-of-Plymouth (Mrs. William Dana Starr wrote in 1900 that the inhabitants of Plymouth were convinced that the Pilgrims of 1620 named the plant *Sabatia* after the Sabbath; they maintained that was the holy day on which they first saw the flower, and that “strong objections are made if any other flowers are irreverently mingled with it in church decorations,” Massachusetts)

According to Greek legend, the Kentauron (Centaur) Chiron was a physician famous for his knowledge of healing plants (Baumann 1993). Among his many feats, this half-man and half-horse was the master of Asclepius and teacher of Achilles. One version of his story has it that he used a *Centaurium* (Gentianaceae) to treat an arrow wound accidentally inflicted on him by Hercules. According to some, confusion by the 16th-century herbalists held that the plants used were *Centaurea* (Asteraceae), another genus

named for the Centaur. Regardless, Chiron is believed to have discovered that *Centaureum* was a blood purifier, and it remains in use today to aid digestion (Baumann 1993, Duke et al. 2002).

Those stories of *Centaureum* were recorded by Theophrastus, 372–287 B.C., but the plant was still famous at the time Europeans arrived in the New World. Spanish speakers called the European medicinal plants *centaurea*, while in Portuguese it was *centáurea*. In French, the plants were *centurée*, in Italian *centauro*, and in English centuary. Germans also considered the plants valuable, but rendered them *Tausendgüldenkraut* (thousand-dollar herb).

When people arrived on the east coast of North America, they found plants similar to *Centaureum*. These herbs were promptly dubbed “centaury.” Linnaeus described two of the Florida species in 1753, *Chironia angularis* and *C. campanulata*, based on specimens collected by his former student Peter Kalm. He too wanted to compare them to the Old World remedies, and chose to dedicate them to *Chiron*. It was only 1763, when Michel Adanson published his *Families des Plantes*, that people realized Linnaeus had included two distinct genera in his *Chironia*. One of the genera remained *Chironia*, a group of about 15 species that grow in Africa and Madagascar. The American plants became *Sabatia*, with 17 species endemic to North America.

According to physician Benjamin S. Barton (1766–1815), *Sabatia angularis* is the plant, “which is called Centory or Centry in Philadelphia, &c., where it is so commonly employed both by physicians and as a domestic remedy in almost every family. ...I believe that no bitter has been more generally prescribed in the United States, in febrile and other affections, than this common American plant, especially since the memorable year 1793 [date of a yellow fever outbreak], when it was much employed in certain stages of yellow-fever; and in which I believe it was very often used with much benefit” (Coffey 1993). The plants were similarly praised by Jacob Bigelow (1787–1879) in his *American Medical Botany*, published in 1817–1820, and by John Eberle (1787–1838) in his *A Treatise of the Materia Medica and Therapeutics* from 1825 (Porcher 1863).

However, it was not until 1831 when the name “American centaury” appeared in the literature. That year, John Davies wrote in his *Manual of Materia Medica and Pharmacy Adapted to British Practice*, “American Centaury... This plant is a pure bitter, justly held in estimation as a valuable tonic and febrifuge.” Porcher (1863) recommended, “The cold infusion of one ounce of the herb to one pint of boiling water, taken in doses of a wineglassful every two hours...or thirty grains to sixty grains of the powder, which also acts as a vermifuge. The decoction, extract, and tincture may be used.” He considered *S. stellaris* as good a remedy as *S. angularis*.

The American centaury was included in the U.S. Pharmacopoeia between 1820 and 1882, and considered a “bitter stomachic, similar in its action to the other gentians” (Vogel 1970, Coffey 1993). This was also one of the *schwitzgegreider* (sweat herbs) the Pennsylvania Dutch mixed into whiskey (Vogel 1970).

The Cherokee are the only indigenous tribe found to have used *S. angularis*. They drank an infusion to treat malaria (Hamel and Chiltoskey 1975). However, Daniel Drake recorded use of *S. angularis* as a febrifuge in the Ohio Valley in 1850 (Vogel 1970). He did not reveal the people using it, but it was perhaps the Shawnee.

Sturtevant (1955) and Moerman (1998) recorded that the Seminoles use *S. campanulata*. That identification is probably not correct, as there was confusion

regarding southern Florida plants dating from Small (1933) until Wunderlin (1998), even though Wilbur (1955) had clarified their distinctive ranges. The plants that were reported by Sturtevant (1955) were from the Big Cypress Seminole Reservation, where *S. campanulata* does not grow. Both *S. stellaris* and *S. grandiflora* are frequent on the reservation, but the one likely to be confused with *S. campanulata* is *S. stellaris*. That is probably what the Mikasuki call *owa:ciká:bi* and the Creeks call *kococompahá:ka*.

*Owa:ciká:bi* is part of a remedy for what the Seminoles call

*ha:słayhi*

(sun shot, Mikasuki), and Sturtevant (1955) dubbed the

*Ha:słayhi*

“Sun Sickness.”

is a malady that strikes in the hot months of May through August. In the early morning the eyes hurt, a headache begins, there is a high fever, and diarrhea. The patient can become blind and even die if not treated (Sturtevant 1955). The roots of *Sabatia* are mixed with *Bidens coronata* and *Persea* in cold water and used in the treatment. See also *Rudbeckia*.

Hocking (1997) listed two other Florida species. *Sabatia bartramii* was not named until it was described by Robert L. Wilbur (1955). Prior to that time, it had been confused with John K. Small’s (1933) *S. dodecandra*. *Sabatia bartramii*, a multipetaled southern Florida herb, is used as a “bitter tonic” to aid indigestion by Seminoles and others (von Reis and Lipp 1982). Similarly, *S. brevifolia* has been used as a substitute for quinine.

*Sabatia angularis* contains the bitter principles erythrocentaurin and gentiopicrotin, which promote appetite and digestion (Lewis and Elvin-Lewis 1977, Hocking 1997). Uphof (1968) and Hocking (1997) say that *S. brevifolia* and *S. campestris* also contain the same bitter compounds. *Sabatia campestris* has long been used by Mexicans and indigenous people of Texas as a “chill tonic” (Hocking 1997). Probably, all the species in *Sabatia* contain gentiopicrotin and the related erythrocentaurin, as those chemicals also have been found in *Enicostema*, *Gentiana*, and *Swertia* (Ghosal et al. 1974, Sluis et al. 1983, El-Sedawy 1989a,b, Menkovic et al. 2000). Indeed, Cronquist (1981) considered the iridoid compounds, particularly gentiopicroside and related substances, characteristic of the Gentianaceae. Perhaps the bitter compounds are why Millspaugh (1893) remarked, “A peculiar property pervades the whole of this natural order—the species when fresh are all emetic and cathartic, and, when dry, tonic, and stomachic in varying degrees.”

### *Sagittaria*

(Linnaeus used the Latin *Sagittarius*, belonging to an arrow, in reference to the leaf shape)

arrow-head [arrowhead] (in use for these plants by John Gerarde’s *Herball* of 1597; the word for the points of arrows, in use by 1483)

*cola de golondrina* (swallow [bird] tail, Spanish)

*erba saetta* (arrow herb, Italian); *erva frecha* (arrow herb, Portuguese); *Pfeilkraut* (arrow herb, German); *fleche d'eau* (water arrow, French); *saeta de agua* (water arrow, Spanish); *sagittaire* (arrow, French)

***Sagittaria landfolia*** (lance-leaf, referring to leaves shaped like a lance point)

*angelito* (little angel, Dominican Republic)

[bulltongue, lance-leaved, scythe-fruit] arrow-head [arrowhead]  
(Florida to Texas)

arrow-leaf [arrowleaf] (Puerto Rico)

*éneas* (copper colored, Hispaniola)

*flecha de agua* (water arrow, Cuba, Puerto Rico); *saeta de agua* (water arrow, Puerto Rico, Panama); *flechera* (arrowhead, Cuba); *flechiere obtuse* (blunt arrowhead, Haiti); *sagitaria* (arrow, Cuba)

*hicakná:bî* (feral-taro replica, based on *hicakní*, for *Colocasia esculenta*, an introduced plant, Mikasuki)

*kibix* (*ki*, henequen fiber, *bix*, uncooked beans, Maya, Belize)

*lirio de sabana* (savanna lily)

*plécoire* (Haiti)

*rabadilla* (little tailed one, Puerto Rico)

*renoncule aquatique* [*des savanes, sagittee*] (water [savanna, sagittate] ranunculus, Haiti)

swamp spaghetti (USA)

***Sagittaria.*** *Sagittaria landfolia* . From  
Institute of Food and Agricultural

Sciences. *Sagittaria latifolia*, a. Habit,  
b. Flowers, c. Achenes. Drawn by  
Regina O. Hughes. From Reed 1971.

*yautía* [*yahutia*, *diahutia*] (first recorded by Bartolome Las Casas, whose copiest wrote *yahubia*, Taino name for *Zanthosoma sagittifolia*, later applied here, Hispaniola)

***Sagittaria latifolia*** (broad-leaved)

[broadleaf, common] arrowhead (Florida)

*çin* (Osage)

duck potato (USA)

*kaishüepenauk* (maybe “loose ground nuts,” i.e., easily dug, Carolina Algonquians; see Geary 1955); *katniss* (Algonquian, probably Delaware, New Jersey); *wabasi’bînik* [*wabasi’-pînik*, *kopî-niak*] (white potato, Potawatomi)

*wappato* [*wappatoe*, *wappatoo*, *whápto*, *wapto*, *wapito*, *wapata*] (recorded in 1807 by Patrick Gass of the Lewis and Clark expedition in the Columbia River region where the word *wapato* is part of the Chinook jargon; probably a loan word adopted by the Cree traders during the fur trade era, who now call it *wapatowa*, white mushroom)

The Glades people living on Lake Okeechobee before the Europeans arrived were using *Sagittaria* (Hogan 1978). Given the rich history of the genus among North American people, they were likely using it for both food and medicine. They had available to them both *S. lancifolia* and *S. latifolia*, with the second species being the more useful of the two. Harriot ([1590] 1972) probably gave the earliest name of *S. latifolia* when he recorded, “*Kaishüepenauk*, a white kind of root about the bignes of hen eggs & nere of that form: their tast was not so good to our seeming as the other.” In his comparison to hen eggs, he did exactly the same as Patrick Gass in 1807 when he recorded the name *wappato*. Gass’s record was from the opposite side of North America, among the Chinookan people the journal called the Skilloot in the Columbia River region of Oregon.

Peter Kalm wrote while in New Jersey in 1749: “*Katniss* is another *Indian* name of a plant, the root of which they were likewise accustomed to eat. ...The *Indians* either boiled this root or roasted it in hot ashes. Some of the *Swedes* likewise eat them with much appetite.” Although Kalm and the Swedish Americans were exuberant about the roots of *S. latifolia*, Morton (1968) was not as pleased with those of *S. lancifolia*. She wrote, “blanched roots edible, but with little flavor;...juiciness is refreshing.” People in the Atlantic states, and extending to Minnesota and Wisconsin are known to have eaten the roots (Gilmore 1919, Hedrick 1919, Densmore 1928, Yanovsky 1936, King 1984). Similarly, Cubans, Chinese, and Panamanians ate the roots, either roasted or made into flour (Roig 1945, Duke 1972).

The Miccosukee name for *S. lancifolia* poses an interesting problem. According to Sturtevant (1955), *hicakna:bi* means “feral-taro replica,” based on *hicaknî*, the name for *Colocasia esculenta*. The Creek name for *C. esculenta* is *hilá*. That plant was unknown to the people in North America until it was introduced from Asia (Smarrt and Simmonds

1995). Perhaps this is another instance of the name of an old food being usurped by a new one. That replacement has been noted for the opossum (*Didelphis virginiana*) in both Cherokee and Mikasuki (Mooney 1885–1886). In Mikasuki the opossum is now *sokihatki* (white pig). Prior to the introduction of the Old World swine, the opossum was *soki*. That name was switched to the pig, and the “white” modifier attached to note the old familiar North American animal (Sturtevant 1955). Cherokee call the opossum *sikwa utse’tsti* (grinning pig); the hog is *sikwa*.

Regardless of its past uses, by the time Small (1933) was studying plants in Florida, the Seminoles had a single use for *S. lancifolia*. He learned that they used the plant to treat shock after an alligator bite, and his notation seems to have been the sole source for Sturtevant’s (1955) entry.

Grimé (1976) found that blacks in Jamiaca used the plant to treat wounds and yaws. In Cuba and Haiti, the roots are used as a rubifacient to stop toothache (Roig 1945, Morton 1981). Crushed leaves are poulticed on infected sores, chronic itch, and snake and insect bites in Panama (Duke 1972).

### *Salicornia*

(Linnaeus used either the Latin derived from *sal*, salt, and *cornus*, horn, referring to the salt-loving plants with hornlike branches, or Arabic *sala-al-qarab*, giving rise to French *salicorne*; given Linnaeus’s tendency to use dual-meaning names, he probably used both)

glasswort (in use since John Gerarde’s *Herball* of 1597)

*salicornia* (probably from from the Arabic *sala-alqarab*, Italian);

*salicorne* (French)

*sosa* (Spanish)

***Salicornia bigelovii*** (named for its discoverer, Jacob Bigelow, 1787–1879, an American botanist)

annual [dwarf] glasswort (Florida, Puerto Rico)

*chifle* (whistle, Puerto Rico)

***Salicornia bigelovii*.** From Britton and Brown 1896.

***Salicornia perennis*** (perennial) (= *S. virginica*)

[American, perennial, Virginia, woody] glasswort (USA, Bahamas)  
Guinea bead (Bahamas)  
pickleweed (USA)  
wild coral (Carolinas, Bahamas)  
*yerba de vidrio* (glass herb, Spanish)

*Salicornia* is used by people all over the world. In Europe, *S. europaea* (samphire, chicken claws, pigeon-foot, glasswort) is pickled in vinegar. An ash called *barilla* was made of it to use in the manufacture of soap and glass, and it is considered diuretic and antiscorbutic (Hocking 1997). East Indians also use *S. brachiata* for carbonate of soda, in manufacturing (Morton 1974). In Australia, *S. australis* shoots are pickled and eaten (Uphof 1968).

Florida species are also cooked and eaten (Morton 1968b). In the Carolinas, a decoction is used to treat colds and for whooping cough (Morton 1974). Gosiute (Utah, Nevada), Heiltzuk (coastal British Columbia), and Salish (Vancouver Island) used them, but no records were found of indigenous people using them in the southeastern United States.

***Salix***

(Ancient name for the willow; possibly related to the Gaelic *suil* for the tree, and Akkadian *salihu*, sprinkler of water)

*accaycay* (Coptic)

*ai-pee-á-'gaw* (Kiowa); *señ-ä* [*señ-ya-daw*] (Kiowa)

*itea* (Greek)

*ittokoowisa* (*itto*, tree, *oki*, water, *homi*, bitter, Alabama); *okawisa* (Alabama); *okoowaykachi* (*oki*, water, *oo-*, within, *wihaachi*=?, Alabama)

***Salix humilis*.** From Britton and Brown 1896.

*jarita* (to cast, as an arrow, from Hebrew *khara*, New Mexico); *xara* (arrow shaft, from Arabic *xara*, New Mexico)

*k'ai* (Chipewyan, Canada); *ka* (Slave, Canada)

*kitapato* (Pawnee)

*nepise* (Cree)

*ozi'sigo'bimic* (Ojibwa)

*ruhi* (Winnebago); *sin-des-nes-ni* (it grows by water; *ni*, water, Osage; also *thiu'-xe*)

*saḡsaḡ* (Arabic)

sallow (from Old English *sealh*, Anglican *salh*, cognate with Old Norse *selja*, Swedish *sålj* [*sålg*], *sålg* (Norwegian), and Danish *selje*; the word is also cognate in languages other than Germanic languages, with Latin *salix*, Irish *salieach*, and Welsh *helyg*; in English by about A.D. 700); saugh (the Old English nominative singular, derived from the Late Anglican *salg* or *salig*; in English by about A.D. 1000); *salgueiro* (from Latin *salix*, Portuguese); *salice* (Italian); *sauce* (Spanish); *saule* (French)

*suil* (the 16th letter of the Gaelic alphabet)

*walipe-popa* (Dakota)

willow (from Old English *welig*, dating to A.D. 750; akin to Middle High German *wilge*, and Greek *helike*); *walg* [*welg*] (Teutonic); *Weide* (German); *wilg* (Dutch); *wylch* or *willig* (Frisian)

*yehiye' yap* (water tree, Catawba)

***Salix caroliniana*** (from Carolina) *ahwá:na:[ahwánv, akawana, ahuane, awannah]* (owv, water, wvnv, string, Creek, Muskogee); *oke bakshe* [*okibaksî, okebakshe, bakshee*] (*oke*, water, *baksî*, string [rope, vine], Mikasuki)

*di-l(i)-ga-li:-s-gi* (Cherokee)

*saule* (French, Houma, Louisiana)

*takoins̄ha* [*tikoin̄sha, takon̄wisha*] (maybe from *itt-ak-owisha* or *itt-ako-wisha*, tree within water, Choctaw)

[coastal plain, southern, swamp, ward] willow (Carolinas to Florida)

***Salix eriocephala*** (cottony-headed, in reference to the fruits)

Missouri River willow

***Salix humilis*** (low)

*hoyanî:cî* (Mikasuki; adapted from Creek); *hoyvnijv* (spreading, alluding to rhizomatous habit, Creek, Muskogee)

*mikko hoyvnijv* [*mikko hoyanî:câ, mikkohoyani:câ, micco hoyonee, micco hoyonvicha*] (*mikko*, chief, *honece*, wild, Muskogee; see Howard 1984)

small pussy-willow

***tcáʔa***

[*tcára*] (Yuchi; still taken as medicinal tea during the Green Corn Ceremony; see Jackson 2003)

[dwarf, gray, prairie] willow

***Salix nigra*** (black)

black willow

*osi* (Koasati)

It was not surprising that Hogan (1978) found willow pollen in the pre-Columbian Glades village on Lake Okeechobee. People around the world have long histories of using willows. In the 1500s, the Glades people were traveling between Key West and Havana in dugout canoes to trade birds and deer skins. The birds were kept in willow cages (Barcia 1565).

From day to day, the Seminoles used the wood to make toy bows for children, sofkee spoons, and stick ball rackets (Bennett 1997). They also constructed chairs and other items from the wood. Dye was extracted from wood and used to color deer hides (Bennett 1997). The Lakota made walking sticks of *Salix eriocephala*, and the Ute used it to make baskets (Moerman 1998). Whitford (1941) found that willow had been used by the Menomini, Winnebago, Ottawa, and Ojibwa to make bags, pouches, fishnets, and cords. He also found the fibers used to make a Micmac fishing spear.

*Eryngium yuccifolium* and *S. humilis* were the two most important plants in the Green Corn Ceremony of the Seminoles, Creeks, and Yuchi (Howard 1984). *Salix humilis* was also important to the Catawba, Cherokee, Delaware, Menomini, and Meskwaki (Hamel and Chiltoskey 1975, Moerman 1998). The plants were used to treat diarrhea, to reduce fever, to treat skin problems, and to stop bleeding.

The Cherokee, Houma, Iroquois, Koasati, and Micmac used *S. nigra* (Taylor 1940, Moerman 1998). The Cherokee used it to treat the same problems as with *S. humilis* (Hamel and Chiltoskey 1975). The Houma used it to reduce fever, and to strengthen a person with "thin blood" (Speck 1941). The Koasati took an infusion to relieve headaches and reduce fever (Taylor 1940).

We have records of the Houma using *S. caroliniana* for weak blood and fever (Speck 1941). As Alice Snow wrote, "It is used for most everything" among the Seminoles (Snow and Stans 2001). The classical use against fever as among the Houma is repeated in species after species (Moerman 1998). There are numerous other uses among the Seminoles of more religious and ritual significance (Sturtevant 1955, Moerman 1998).

***Salvia***

(Latin *salvus*, whole, well-preserved, safe; akin to Akkadian *salwu*, healthy, Persian *haruwa*)

***Salvia lyrata*.** From Britton and Brown 1898.

*athair liath* (father gray-hair, Gaelic)

clary (from Old English *slaric*, changing to *claré* in the 1500s; still *sclarée* in French, from Latin *sclarea*; originally applied to *Salvia sclarea*, Lamiaceae; since about A.D. 1000 variants of the word “clary” have existed, and this aromatic mint of southern Europe was used to adulterate wines, as a condiment, and as a medicinal herb; in the 1500s, the name also was transformed into “clear-eye,” “Godes-cie” [good-see], and “see-bright” to emphasize its use for treating eyes)

*sàisde* [*sàiste*] (from Latin *salvia*, Gaelic); *Salbei* (German); *salva* (Portuguese); *salvia* (Italian, Spanish); *salvie* (Norwegian); *sauge* (French); *savie* [*salve*] (Dutch)

*torman* (based on *tormach*, increase, Gaelic)

***Salvia lyrata*** (lyre-shaped)

cancer-weed [cancerweed] (first used in 1546 for various plants to cure “cancer,” not always applied in its sense of being a malignant growth; name used by Williams [1837] 1962; well established in South Carolina as a name by the time of Porcher 1863)

lyre-leaf sage [lyre-leaved sage]

meadow [wild]-sage

Europeans had a history of using *Salvia* as medicine dating to the classical Greeks and Romans, and probably earlier. Pliny (A.D. 23–79, Dioscorides (A.D. 40–80), Aëtius (A.D. 527–565), and Paul of Aegina (A.D. 625–690) discussed what we now know as *Salvia fruticosa*, *S. officinalis*, *S. pratensis*, and *S. sclarea* (Meyer et al. 1999). Fuchs in 1542 (Meyer et al. 1999) and later herbalists also commented on those European species. The very name “*Salvia*” reflects their importance (de Cleene and Lejeune 2002).

The most popular among the sages in early Europe was *S. officinalis*. Of that species, John Parkinson wrote in 1629, “Sage is much used of many in the month of May fasting, with butter and Parsley, and is held of most much to conduce to the health of a mans

body.” Not much later John Evelyn wrote in 1699 that “tis a plant endu’d with so many and wonderful properties, as that the assiduous use of it is said to render men Immortal.”

Indigenous Americans also had a rich history of incorporation of *Salvia* into their lives. Moerman (1998) listed 7 species used in North America, but that is probably an underestimate. Historical records are also biased toward the western United States, perhaps partly because of the greater number of indigenous species there. For example, Fernald (1950) listed only 4 native species in the northeastern states, while Kearney and Peebles (1951) recognized 14 from Arizona alone.

The widespread *S. lyrata* is the most common species in the eastern states. This sage ranges from Pennsylvania to Florida and west to Texas, south-eastern Kansas and Illinois. The Catawba made a salve from the roots to treat sores (King 1984). The Cherokee took an infusion to treat diarrhea, colds, nervous debility, and phlegmatic individuals (Hamel and Chiltoskey 1975); they used the same preparation to strengthen women and as a laxative. The Cherokee also mixed the leaves and flowers with honey and drank it to relieve asthma. Since they did not have honey before the introduction of the bees (*Apis mellifera*), that was either a modification of an old remedy, or one they learned from Europeans. Porcher (1863) wrote, “The fresh radical leaves of the plant, when bruised and applied to warts, generally destroy them; continue the application for a day or two, and renew it every twelve hours.” Seeds were also made into an ointment to cure wounds and sores (Coffey 1993).

### ***Sambucus*: Elders**

(Derivation uncertain, may be from Greek *sambuce*, a musical instrument; more details in discussion)

Few people in the United States will understand if someone calls a plant an “elder,” although they would if it is called an “elderberry” (USA to Virgin Islands). The word “elder” is applied to what scientifically is *Sambucus*. Both words have complicated histories.

“Elder” has been in English since at least A.D. 700, when it was spelled *ellaern* or *ellen* (Old English) or *ellern* (Anglo-Saxon). Related words in Middle Low German were spelled *elderne*, *alhorn*, or *elhorn*. Genders (1988) said those words were cognate to Saxon *aeld* (fire), because the hollow stems were used to kindle campfires, but that is dubious. Germanic Europeans were afraid to burn elder wood. De Cleene and Lejeune (2002) offer a more likely etymology.

Cognate name of the shrubs are *hyld* (Danish), and *hyll* (Swedish and Norwegian), and these are related to *Holle*, *Holunder*, *Holder*, or *Elhorn* (German). Those names and the Danish *Hyldemör* or *Hyllefrao* allude to Freya, who was the Norse goddess of fertility, and the most revered of all goddesses. She was called *Vrouw Arda*, *Vrouw Herta*, or *Vrouw Holle* in the Netherlands. This “Lady Elder” lived in an elder and became the symbol of reincarnation. She and the plant represent the European “Tree of Life.”

Unhappily, the etymology of *Sambucus* is not as easily unraveled. *Sambucus* was once thought to be from Greek *sambuce*, an ancient flutelike musical instrument made from the readily removed tubes of bark (Fernald 1950). Recent suggestions are that *Sambucus* may have come from *sambuca* [*sambuke*, *sambuc*] (Latin *sambúca*, Greek *sambúka*,

cognate to Aramaic *sabbeka*) “a triangular stringed instrument with a shrill tone” (OED 1971). Some say these musical instruments were made from the wood of elders (Walker 1976, Kowalchik and Hylton 1987). Quattrocchi (1999) was uncertain, saying Latin *sambucus* and *sabacus* were used by Pliny for an elder tree. The Portuguese name *sabugueiro* comes from *sabugo*, taken from Latin *sabacu*. Could all these words be related to Greek *sabakos*, rotten, because of the unpleasant smell of the foliage? Regardless, *Sambucus* has cognates in *sureau* [*siriyo*, *suyeau*] (French, Trinidad), *sambuco* (Italian), *saúco* (Spanish), and *sabugueiro* (Portuguese), although *senboqua* (Arabic) might be a loan-word.

***Sambucus nigra* ssp. *canadensis*.**

From Institute of Food and  
Agricultural Sciences.

Other European languages also have names for elders, because there are three native species there. Before arriving in the New World, Europeans had long histories of interacting with *S. ebulus*, *S. nigra*, and *S. racemosa*. These have their own complicated name history.

The best known of the three is *S. nigra*, and it is called elder (English), boor [boer, bour] (akin to arbour and bower, British Isles), *sureau* (French), *sambuco* (Italian), *saúco* (Spanish), *sabugueiro* (Portuguese), *Holunder* (German), *vlier* (Dutch), and *svarthyll* (black elder, Norwegian). *Sambucus nigra* formed the 15th letter of the Gaelic alphabet as *ruis*. Hermann Boerhaave (1668–1738), the famous Dutch physician, is said to have held the *vlier* in such regard that he doffed his hat each time he passed it (Curtin 1947, Kowalchik and Hylton 1987). Supposedly, he did that not only because of his high regard for the plants, but also because European folklore required reverence in the presence of the elder. Vickery (1995) found *Sambucus* to be one of the “most enigmatic plants in

British folk tradition.” The plants are feared and associated with witches (it belongs to them and repels them), yet valued for its protective qualities as a fly repellent and in herbal remedies.

The “elder” in Florida is often called *S. canadensis*. It also goes under the English names American elder (USA), southern elderberry, elder-blow (USA, “blow”=blossom, related to German *Blume*), garden elder (USA), sweet elder (USA), West Indian elder (Barbados), and white elder.

However, determining what species are in North America turns out to be more complicated than is at first apparent. The most recent examination of the species is that by Bolli (1994) who made most American plants subspecies of *S. nigra*. Hence, Florida plants are *S. nigra* ssp. *canadensis*. Although Wunderlin (1998) uses *S. canadensis*, Stevens et al. (2001) adopt *S. nigra* ssp. *canadensis*. Plants in the south-western United States and northern Mexico are *S. nigra* ssp. *cerulea* (Felger et al. 2001, Hodgson 2001). My discussion also follows Bolli (1994).

Elderberry, in this broad definition, ranges through the eastern woodland part of the United States and is disjunct across the Great Plains into western North America from Canada south through Mexico, Mesoamerica, and the West Indies, to Peru and Veneuela. In Spanish, this large shrub or small tree is *capulín silvestre* (wild cherry, New Mexico), *chacuaco* (maybe from *tzacualli*, shortcut, Náhuatl, New Mexico), *flor de sauz* (elder flower, New Mexico), *saúco* (Mexico to Panama), *saúco blanco* (white elder, Cuba), *saúco Colorado* (red elder), *saúco extranjero* (foreign elder), or *tápiro* (Sonora and Arizona). French speakers say *sureau [blanc]* ([white] elder, Canada, France, French Antilles) or *fleur sureau* (elder flower, Haiti).

Numerous indigenous people in Mexico also name these plants. To the Aztecs, they were *xomatl* [*xumatl*, *xumetl*, *azumiatl*] (Náhuatl, Veracruz). That name is akin to *bixhumi* [*bahman*, *bajman*] (*bi*, fruit or leaf, *xhumi* from Náhuatl *xomatl*, elderberry, Zapotec, Oaxaca). Elsewhere, they are *tsolos-che'* (*tsolos*, smooth, *che'*, tree, Maya). Tarahumara say *ñe ho* (Chihuahua). Although introduced in Yucatan, the Maya also call them *sak'ah-tsum* [*sacatsun*] (*sak'*, white, *ah-tsum*, male turkey). That name is given because they think the fleshy excrescence on the male turkey beak resembles the inflorescence. The remaining names appear to be simple terms, including *coyopa* (Zoque), *condumbo* [*cumdemba*, *cumdumba*] (Tarascan), *nttizrza* (Otomí), *shiiksh* (Mixe), and *yutnucate* (Mixtec).

We have records of the eastern ssp. *canadensis* being used by the Algonquin, Cherokee, Chickasaw, Choctaw, Creek, Dakota, Delaware, Houma, Illinois, Iroquois, Menomini, Meskwaki, Micmac, Mohegan, Ojibwa, Omaha-Ponca, Osage, Pawnee, Rappahannock, Sauk-Fox, and Seminoles. The western ssp. *cerulea* was used by the Cahuila, Chehalis, Clalla, Costanoan, Diegeño, Hiá-ced O'odham, Karok, Klallam, Klamath, Kawaiisu, Luiseño, Lummi, Maricopa, Mendocino, Mewuk, Miwok, Navajo, OkanaganCoville, Paiute, River Pima, Pomo, Quinalt, Salish, Skagit, Skokomish, Squaxin, Thompson, Tohono O'odham, Yavapai, Yokut, Yuki, and Yurok (King 1984, Kay 1996, Moerman 1998, Hodgson 2001). The Dakota called elderberry *cahupta* or *chaputa-hu* (elder bush). To the Omaha-Ponca, they were *wagathahaskha* or *wagathahaskha-hi* (elder bush). *Skirariu* was the Pawnee name (Gilmore 1919). The Plains Cree called them *kehte'mina*. They are *hauku'usi* to the Mountain Pima, and

*dahapdam* to the Akimel O'odham or Gila River Pima (Kay 1996, Rea 1997). To the Choctaw they are *bashankchi*, and the Chickasaw say *basho'kchi'* [*basho'chi'*].

In Florida, these useful plants are known as *tá:bó:cí* (small elder, Mikasuki) and *coskílpa* [*echoskelepv*, *tcokiliba*] (*coskelepv*, Creek). Martin and Mauldin (2000) reported

the names *ɬvʈo* [*rvro*] *em pvtake* ( *ɬvʈo*, fish, *em pvtake*, its bed) and *hakkv hakv* (*hakkv*, spoon, *hakv*, resembling) for *Sambucus*. The first name referring to fish surely denotes an observation that fish like to lie in the shade of these streamside bushes. The second perhaps means that the wood was useful for carving spoons.

Sturtevant (1955) reported the elderberry being used by the Seminoles in a medicine to treat stomach-aches, and as blowing tubes, toy blowguns, and scarcity food. The Iroquois treated fever with infusions made from elderberry bark or berries, and used them as a pain killer and anti-inflammatory (Vogel 1970). The Choctaw combined elderberry leaves with salt for a headache poultice (Bushnell 1909). The Creeks pounded roots, stirred them in hot water, and bound them on women who suffered from swollen breasts (Swanton 1928a). The Houma used them as an anti-inflammatory (Speck 1941), and bark tea was applied in difficult childbirth. The Menominis used dried flowers as an antipyretic (Smith 1928). Berries were considered official in the U.S. Pharmacopoeia from 1820 to 1831 and formed the base of a refrigerant and diuretic drink. Flowers were in the U.S. Pharmacopoeia from 1831 to 1905 and in the National Formulary from 1916 to 1947 (Millspaugh 1892, Kowalchik and Hylton 1987). Root decoctions were considered a cure-all in South Carolina (Morton 1974).

At least some of the active compounds leading to such widespread use of *Sambucus* as a medicine are the cyanogenic glycosides (Foster and Duke 1990, Buhrmester et al. 2000). They also contain astragalin, kaempferol, rutin, sambunigrin, and tannins (Kay 1996). Roots, bark, leaves, and unripe berries contain these toxins, and they are not safely consumed without preparation. In addition, the plants contain chemicals that are antiviral, at least to tobacco viruses (Chen et al. 2002). Other studies indicate the plants are not just poisonous, but truly medicinal (Chichon 2000, Seeram et al. 2001). Plants have anti-inflammatory, antibacterial, diuretic, diaphoretic, and laxative properties (Kay 1996). Duke et al. (2002) give it three plusses, safer than coffee.

Flowers are nontoxic, and eaten in pancakes, fritters, cooked in scrambled eggs, or made into teas and other beverages. Tea has been considered a mild stimulant, carminative, and diaphoretic, as well as good-tasting. Cooking detoxifies the glycosides and renders the cyanide harmless, so fruits are safely made into tarts, pies, jams, chutneys, preserves, and wine (Kowalchik and Hylton 1987). The Italian liquor *sambuca* is flavored with elder berries.

Additionally, the berries contain anthocyanins that have been used since at least the time of classical Greece for dyes (Johansen et al. 1991, Nakatani et al. 1995). Pan, the Greek god of shepherds, is reputed to have dyed his hair black with elderberries (Kowalchik and Hylton 1987). The berries also have been used since the Greeks and Romans to color wine (Baumann 1993). Adulterating wine got so bad in Portugal it became illegal to grow elderberries (Kowalchik and Hylton 1987). Leaves also have been included to impart a clear green tint to medicinal oils (Millspaugh 1892). The berries produce violet, blue, purple, lavender, blue-green, gray, brown, yellow-tan, and deep

forest green shades for wool, baskets, or meat stamp dyes (Kowalchik and Hylton 1987, Tull 1999). Flowers have been added to perfumes (Millspaugh 1892).

Europeans and Americans formerly would have understood if you asked which tree was the “country medicine chest.” Now, wholesale drainage and falling water tables in the United States have made the plants rare. Just at a time when herbal medicine is in a renaissance, some are realizing too late that it was worthwhile to have wild and wet areas with their animals and plants.

### *Samolus*

(An ancient Latin name for plants used by Druids, said to refer to curative traits of this genus in diseases of cattle and swine; it may be Gaelic, from *sabh*, ointment or salve, or *samh*, fat, and *lus*, plant)

*Samolus ebracteatus*. a. Habit, b. Outer surface of flower to show reflexed petal, c. Corolla spread out, inner surface, d. Mature fruit with pistil attached to one segment. Drawn by Vivian Frazier. From Correll and Correll 1972.

brookweed (dates from ca. 1624, Europe)

*Bunge* (German)

***Samolus ebracteatus*** (without bracts)

*espuela de caballero* (gentleman's spit, Cuba)

larger water-pimpernel [water pimpernel] (USA, Bahamas); pimpernel ("pimpernel" came from Medieval Latin *pipinella*, which perhaps came from *bipinella*, a diminutive of *bipennis*, two-winged, apparently in reference to *Pimpinella*, Apiaceae)

limewater brookweed (Florida)

***Samolus valerandi*** (presumably from Latin *valeo*, be strong, plus *-andi*, full of, or "full of strength")

*alface dos rios* (river lettuce, Portuguese)

[common] brookweed (Europe, USA); seaside brookweed

*ehitiil ithim palats* (like *Lobelia berlanderi*, Huastec, San Luis Potosí)

*mouron-d'eau* (water pimpernel, French)

*palplina de agua* (touching water, Spanish)

pineland pimpernel; water-pimpernel (Bahamas)

*Salzbunge* (salt pimpernel, German)

*samolo* (Italian); *strandamel* (*strand*, seashore, *samel*, pimpernel, Norwegian)

This is another medical plant that Hogan (1978) found at the pre-Columbian Glades village at Fort Center. Hers, however, apparently is the only record of indigenous use of the plants in continental North America. Nearby in Cuba, *Samolus* is considered antiscorbutic and diaphoretic and is sometimes eaten in salads or as emergency food (Roig 1945). Although no use is given for *Samolus*, its Huastec name associates it with an edible plant, suggesting that it too was eaten (Alcorn 1984).

### ***Sanguinaria***

(Latin *sanguinarius*, bleeding, based on *sanguis*, blood, from the color of the juice)

***Sanguinaria canadensis*** (of Canada)

*achtuchwiminschi* (*achtuch*, red, *minschi*, plant, Delaware)

bloodroot (originally applied by 1578 to a *Geranium* in Europe and then reapplied to this New World plant)

*Blutwurz* [*Blutwurz*] (blood herb, German)

[red] Indian-paint

large-leaved sandwort

*meskwaspenn* (Capt. John Smith and Strachey wrote in 1612 wrote of *musquaspenn*, "a root of the bigness of a finger, and as red as blood... in drying, it will wither to almost nothing... they use to paint their mats, targets, and such like"; Siebert 1975 reconstructed it to ancestral

*Sanguinaria canadensis*. From Britton and Brown 1897.

Proto-Algonquian *meçkwaxpenya*, “red root”); *mis’kodji’bik* (*mis’ko*, red, *dji’bik*, root, Ojibwa); *maskwa’we* [*mêskwa*] (red, Prairie Potawatomi); *mackwasdji’bîkûkûk* (*mackwas*, red, *dji’bik*, root, *ûkûk*, plant, Potawatomi)

*minigathe makan wau* (*wau*, woman, *makan*, medicine, *minigathe*, seeking, Omaha-Ponca)

*panson* [*pauson*] (variant of “panse,” a word from French *panser*, to take care of the sick or treat wounds)

*peh-hishuji* (*peh*, gourd, *hishuji*, to make red, probably referring to use for coloring gourds rattles, Winnebago); *shu-jee-hu* (*zhu-dse*, red, *hiu*, plant, Osage)

*pishkak* [*pishuk*, *pishaiyik*] (Choctaw; it is not clear that this name refers to a single species; may be *Sanguinaria*, *Lachnanthes*, and/or *Lithospermum*); *hahtok* (Chickasaw)

[red] puccoon [*pochones*, *pochoon*] (Strachey recorded the Powhatan in 1612 as *poughcone*, “red paint or dye,” *pokcoons*, “a red dye,” and *pocones*, “small root that grows in the mountains, which being dried and beat in powder turns red”; Siebert 1975 found cognates in Penobscot *pákahkan*, Mahican *pkáhhkan*, and Nanticoke *pakahk*, all meaning “blood”); coonroot [*coonroot*, *cornroot*] (“coon” is an abbreviation of “puccoon;” and “corn” a corruption of that, West Virginia)

redroot (used by John Bartram, 1751, Maine)

*sang-dragon* (dragon blood, Quebec); *sanguinaire* (bleeding, Quebec)

snake-bite (New Hampshire)

sweet-slumber (Pennsylvania)

tetterwort (“tetter” from Old English *teter*, first used about A.D. 700; various skin diseases including ringworm, eczema, and herpes;

“tetterwort” first applied to *Chelidonium majus* ca. 1400–1450; later to *Sanguinaria*, in the same family)

tumeric [tumerick] (used by John Bartram, 1751, Pennsylvania; the real tumeric is *Cucurma longa*, Zingiberaceae, and it too gives a red color)

white-puccoon (a compound name noting that this “puccoon” has white flowers, New York)

*wi·ti· sak a' ?* [*si ?k á, ske*]  
*sak a' ?*,  
 (wi·ti, root red, Catawba);  
*wayu'k te' ?*  
 (Catawba)

Probably the first published record of *Sanguinaria* was by Capt. John Smith in 1612, when he wrote that the Virginia Powhatan used it for dyes. Their red dye came from the “Pocones,” which “is a small roote that groweth in the mountaines, which being dried and beate in powder turneth red: and this they use for swellings, aches, annointing their joints, painting their heads and garments.” Later people confused the origin of red dyes taken from *Sanguinaria* with *Lachnanthes*. Robert Beverley in 1705 wrote, “*Smith* talks of this *Puccoon*, as if it grew on the Mountains, whereas it is common to all the Plantations of the English” (Swanton 1946). Actually, Smith was writing about *Sanguinaria* while Beverley was describing *Lachnanthes* (which see).

William Strachey, also writing in [1612] 1953, said of the Virginia people: “They are generally of a cullour browne or rather tawny, which they cast themselves into with a kind of arsenick stone, like red patise or orphement, or rather red tempered oyntments of earth, and the juyce of certaine scrued rootes, when they came unto certaine yeares, and this they doe (keeping themselves still so smudged and besmeered) eyther for the custome of the countrye, or the better to defend them (since they goe most that naked) from the stinging of muskitoes, kinds of flies or biting gnatts... for which they daily anoint both face and bodyes all over...as can cast them into that stayne. ...Their head and shoulders they paint oftenest, and those red, with the roote of pochone, brayed to powder, mixed with oyle of the walnutt, or bear’s grease; this they hold in sommer doth check the heat, and in the winter armes them in some measure against the cold.” Beverley added that the body painting also aided them against “all Lice, Fleas, and other troublesome Vermine.” Various people used a mixture of roots of puccoon, wild angelica (*Angelica atropurpurea*), and bear oil to repel vermin and to retain skin moisture and reduce perspiration (Vogel 1970).

Perhaps the painting of their bodies led to the adoption of the term “redskins” that persists as the myth that the indigenous people of the New World had skins that color. Apparently, the first use of “redskins” dates from 1699 with “Ye firste Meetinge House was solid mayde to withstand ye wicked onslauts of ye Red Skins” (OED 1971). It is surely significant that forest tribes also used red face and body paint during war (Swanton 1946).

In Florida, the de Soto expedition found Timucua men near Tampa Bay using red body paint (Swanton 1946). Bartram ([1791] 1958) found the head, neck, and chest of the Creeks, Seminoles, and Cherokee painted with vermilion. James Adair found the Chickasaw similarly colored in 1775 and was told by the traders that the quantity of color was an estimate of a man's wealth (Swanton 1946).

Red face paint had special significance among the women. Capt. John Smith wrote, "at night where his lodging is appointed, they set a woman fresh painted red with Pocones and oile, to be his bedfellow" (Vogel 1970). The chaplain traveling with William Byrd's surveying party, drawing the line between North Carolina and Virginia in 1729, was bothered that these ladies, "colour'd with pochoon," visited the men (Vogel 1970). William Bartram ([1791] 1958) wrote that Creek women "never paint, except those of a particular class, when disposed to grant certain favors to the other sex." Among the Yuchi, only unmarried women who were willing to grant sexual favors painted their faces, and then they put "a circular spot in red, about one inch across, on each cheek" (Swanton 1946).

Puccoon, with various spellings, was most often identified as the plant source of the red coloring. While there were at least four "puccoons" (*Lachnanthes*, *Lithospermum*, *Phytolacca*, *Sanguinaria*), the one that has become most associated with the name is *Sanguinaria*.

The first scientific record of *Sanguinaria* was made by Frenchman Jacques Philippe Cornut (1626–1651) in his *Canadensium plantarum historia* (History of Canadian Plants) published in 1635. Cornut used the phrase name *Chelidonium majus canadense acaulon* (large stemless celandine from Canada). That name was subsequently repeated in lists of European cultivated plants including Robert Morrison's *Plantarum historia universalis Oxoniensis* (Universal History of Plants Cultivated at Oxon) published in 1669, and John Ray's *Historia plantarum* (History of Plants) appearing in 1686–1688. If either of these authors knew more about the plants than their curious blood-red roots, nothing was mentioned.

It is now known that *Sanguinaria* is a monotypic genus related to poppies (Papaveraceae) endemic to the deciduous forest region of the eastern United States (Mabberley 1997). The genus was created by Dillenius in 1732 in his *Hortus Elthamensis* and adopted by Linnaeus in 1753. Linnaeus simply emphasized the first locality he knew for the plants by adopting *canadensis* from Cornut's phrase name.

Indigenous people colored items other than their skins with *Sanguinaria*. The Natchez colored textiles red, and they and the Creeks colored baskets made of split cane (*Arundinaria*). Le Page Du Pratz noted red among the colors of cane mats among the Natchez in 1758. Mark Catesby (1731–1743) found people in Virginia and the Choctaw and Chickasaw making colored cane baskets. To the Chickasaw these were *oski' tannafo'* (*oski'*, cane, *tannafo'*, basket), while to the Alabama they were

*iʔanikolbi iʔani*, cane, *kolbi*, basket).

Le Moynes's illustrations of the Timucua show a variety of basket types, some containing red-stained gourds (Swanton 1946). Animal skins were colored red at Cofitachequi, and in Mississippi canoes were that color, among several others (Swanton 1946). Mark Catesby (1731–1743) said that the people of the Carolinas made garters and sashes of hair from buffalo (*Bison bison*) and raccoon (*Procyon lotor*), "which they dye

black and red.” Houma women on the lower Mississippi wore clothing colored red, yellow, and white (Swanton 1946).

As important as *Sanguinaria* was for coloring, it was more significant as medicine. There are records of the herbs being used medicinally among the Abenaki, Algonquin, Cherokee, Delaware, Iroquois, Malecite, Menomini, Meskwaki, Micmac, Mohegan, Ojibwa, Onondagas, Osages, Penobscot, Ponca, Potawatomi, Quapaws, Rappahannocks, Sauks, Shawnees, and Tuscaroras (Gilmore 1919, Densmore 1928, Smith 1933, Vogel 1970, Moerman 1998). These people used the root to treat asthma, bronchitis, burns, fevers, laryngitis, lung ailments, rheumatism, toothache, and warts, among other maladies (Foster and Duke 1990, Moerman 1998, Duke et al. 2002). They considered the extract an appetite stimulant, arterial sedative, and emetic.

Because the Virginia settlers were in infrequent contact with Europe, they relied on indigenous remedies, including bloodroot (Vogel 1970). Jonathan Carver traveling in the “Interior Parts of North America” between 1766 and 1768 called bloodroot, “a strong emetic, but a dangerous one.” George H. Loskiel (in *History of the Mission of the United Brethren*) and physician Mannasah Cutler agreed. William Downey wrote a dissertation on puccoon or bloodroot to obtain his medical degree at the University of Pennsylvania; it was edited by physician B.S. Barton prior to 1808 (Vogel 1970). Self-proclaimed “Indian” physician Robert D. Foster included blood-root in his remedy for croup (Vogel 1970). John Goodale Briante who studied with the “St. Francis tribe of Indians, at Green Bay,” with the Potawatamis, and other tribes used bloodroot in a medicine called *was-amos*. He claimed to cure cancer with the remedy in 1870.

*Sanguinaria* was official in the U.S. Pharmacopoeia between 1820 and 1926 and in the National Formulary from 1926 to 1965. It was considered an expectorant, emetic, tonic, and alterative (Vogel 1970). However, depending on the person, emesis is effected by doses from 30 mg to 1 g of root (Duke et al. 2002).

After intensive study in the 1970s and 1980s, the U.S. Food and Drug Administration declared *Sanguinaria* an unsafe herb (Duke 1985, Bennett et al. 1990, Kiger 1997). Duke et al. (2002) consider the herbs poisonous and recommend against their use.

In spite of these recommendations against *Sanguinaria*, the plant contains at least three chemicals with demonstrated bioactivity conforming to historical use by indigenous people (Lewis and Elvin-Lewis 1977). The isoquinoline alkaloid sanguinarine has demonstrated antibacterial activity that reduces caries. At least one modern brand of toothpaste contains sanguinarine. Historically, *Sanguinaria* was used in one of the most effective cancer remedies known (Lewis and Elvin-Lewis 1977). After learning of the use among indigenous people around Green Bay, Wisconsin, a cancer remedy was created by J.W. Fell in 1857. That treatment was tested in Middlesex Hospital in London. The Fell techniques have been associated with remission if not actual cures because two of the active compounds in the remedy are sanguinarine and chelerythrine. The third chemical, protopine, slows the rate of cardiac contraction (bradycardia) and has been applied for that purpose.

Because of the similarity of the sap to blood, there were also mystical beliefs associated with *Sanguinaria*. The Penobscots wore a necklace of bloodroot, believing that it prevented bleeding because of the red juice it contained (Vogel 1970). The Tuscaroras used *Sanguinaria* for divination (Vogel 1970). The Ponca put some of the root on their hands and contrived to shake hands with a woman they wanted. If

successful, they believed that the woman would marry them within 5 or 6 days (Gilmore 1919).

Sitting on one of my bookshelves is a Cherokee basket dyed with walnut and redroot. The weavers used walnut (*Juglans nigra*) to produce chocolate brown and redroot (*Sanguinaria*) to create reds that have faded to rust. It is a pleasant reminder of colors of ancient usage and symbolically links me with my heritage of people using these dye plants.

### *Sanicula*

(Name derived from Latin *sanare*, to heal, and *culus*, diminutive, alluding to the medical properties; the plants were formerly in great demand for healing wounds)

***Sanicula canadensis*.** From Britton and Brown 1897.

*bodan coille* (*bodan*, penis, *coille*, woods, Gaelic)

*erba frangolina* (brittle herb, based on *frangere*, to break, an archaic form alluding to the brittle stems, Italian)

*sanicle* (from Latin *sanicula*, French); *sanicola* (Italian); *sanicula* (Portuguese, Spanish); *Sanikel* (German, Norwegian); *Saniket* (German); *senikel* (Dutch, in use by 1543)

self-heal (a name given to a variety of plants believed to have great healing properties, including *Prunella vulgaris*, Lamiaceae, *Sanicula europaea*, Apiaceae, and formerly to *Pimpinella saxifraga*, Apiaceae; the name began being used about 1387)

***Sanicula canadensis*** (of Canada)

Canadian black snakeroot [blacksnakeroot] (“snakeroot” has been used as a name for medicinal plants since at least 1635, but originally applied to either *Polygala senega* or *Aristolochia serpentaria*; later applied to other plants)

*mukkude 'widji 'bik* (*mukkude 'wi*, black, *dji 'bik*, root, Ojibwa)

[Canada, Canadian] sanicle (“sanicle” from Old French *sanicle*, first used in the 12th or 13th centuries for *S. europaea*; the modifier distinguishes the New World species)

***Sanicula marilandica*** (of Maryland)

[Maryland] black snakeroot [blacksnakeroot] (a name also given to *Cimicifuga racemosa*, Ranunculaceae)

pool-root [poolroot] (by analogy, a plant with a medicinal root growing beside a pool of water; first applied by 1890 to *Ageratina altissima* by John S. Billings in *The National Medical Dictionary*; later [or before?] applied to *Sanicula*)

[American, black] sanicle

self-heal (application of the Old World name to the New World species)

***Sanicula odorata*** (fragrant)

cluster sanicle

***Sanicula smallii*** (named for its discoverer, John Kunkel Small, 1869–1938, cf. Austin et al. 1987a)

Small’s black snakeroot [blacksnakeroot] (a book name)

German physician Leonard Fuchs wrote in 1542 of what we now call *Sanicula europaea*: “It has been learned from experience that the juice of *Sanicula*, as a drink, remarkably benefits wounds. It is also agreed that the soaked herb, applied to tumors, stops them, or even the juice, rubbed on man or cattle. And, there is no better remedy when disease strikes throat or lungs. In short, *Sanicula* excels at everything *Symphytum* [Boraginaceae] does. It particularly helps the spitting of blood, dysentery, and kidney ailments” (Meyer et al. 1999). That was essentially the attitude of Europeans regarding *Sanicula* when they arrived in the New World.

In the Americas, the Europeans found numerous other kinds of *Sanicula*. Kartesz (1994) included 22 species for the United States, Canada, and Greenland. Fernald (1950) had 5 species in the northeastern states; 4 are in Florida (Wunderlin 1998).

There is a substantial problem in sorting out which of these plants might have been used by indigenous people. As Vogel (1970) pointed out in detail, a prevailing name for *Sanicula* is “snakeroot.” That common name has been applied to so many genera in so many ways that we probably have information on but a small part of the historical accounts of *Sanicula*. For example, Romans ([1775] 1961) wrote that “snakeroots” were used in the South to treat malaria. Similarly, Greenlee (1944) wrote that Florida Seminoles boiled “snakeroots” in a pot and drank it for stomachache. *Sanicula marilandica* has been used to treat fever; *S. smallii* was used for stomach problems (Moerman 1998). Still, there is no way to know which of the half-dozen or so genera those “snakeroots” might be.

Moerman (1998) has sorted out the references that give enough information to be sure that they refer to *Sanicula*. All of the Florida species of *Sanicula* have been used by

people within their range. The Ojibwa made a decoction of powdered *S. canadensis* root to regulate menses and to use after childbirth (Moerman 1998). The Houma made a root decoction for heart trouble (Speck 1940).

The Iroquois applied *S. marilandica* as an emetic to counteract poisons, to cure sore navels, for dropsy, as a laxative, and to treat venereal disease. The Malecite used an infusion of roots to correct irregular menstruation. They also thought *S. marilandica* was used by sorcerers for evil purposes. The Micmac used roots to regulate menses, to stop menstrual pain and rheumatism, to aid in parturition, for kidney trouble, and to treat snakebite. The Ojibwa treated fever with the roots and put pounded root on rattlesnake bite (Moerman 1998). Huron Smith wrote of the Ojibwa, “if this root be chewed it would cause eruptions on the epithelial lining of the mouth. They consider it a very potent remedy” (Coffey 1993).

*Sanicula odorata* was made into an infusion with spikenard (*Maianthemum racemosum*) to relieve back and side pain and kidney trouble in Malecite women. Menomini sorcerers used that species for evil. Meskwaki used it as an astringent and to stop nosebleed (Moerman 1998). The only known use of *S. smallii* was by the Cherokee who drank an infusion with pink lady’s slipper (*Cypripedium acaule*) to treat stomach cramps and colic, and used the liquid as a liniment (Hamel and Chiltoskey 1975).

Several other allusions to indigenous uses are not confirmed in other sources. For example, George H. Loskiel, in *History of the Mission of the United Brethren* published in 1794, recorded that “Canadian sanicle” was used by “Indians” (Vogel 1970). André Michaux wrote on 18 August 1795 that a decoction of *S. marilandica* roots was a sovereign remedy for venereal diseases. Michaux did not state if he found indigenous people or American settlers using the plant (Vogel 1970). Porcher (1863) wrote of *S. marylandica*, “The Indians used it as we do sarsaparilla in syphilis, and also in diseases of the lungs.” Millspaugh (1892) did not include the genus, and Duke et al. (2002) discussed only *S. europaea*.

Foster and Duke (1990) note that the leaves of *S. canadensis* contain allantoin as does *S. europaea*. That compound is apparently effective for treating bruises and inflammation (Hocking 1997). Presumably, that species and the others are likely to contain the chemicals known from the Old World plants. *Sanicula europaea* contains saponins, resins, and tannin-bitter substances (Hocking 1997).

### ***Sapindus*: Soap-Berry**

(Latin *saponis*, soap, and *indicus*, from Indians)

***Sapindus saponaria*.** From Sargent 1905.

Soap. We use it dozens of time each day, and never think about it. It is just there, along with other “essentials.” It took the Old World lifestyle to invent the product. Soap requires alkaline bases, like wood ashes, and fat, originally from swine. Their mixture over heat and subsequent cooling allows them to harden into a lathering, cleaning material.

Soap has been a part of European lives for so long there is little variation in their words for it. Our first English records as *sápe* come from about A.D. 1000. Related Germanic languages like Dutch use *zeep*, German *Seife*, Norwegian *saapa*, and Finnish *saip(p)io*. The Romance languages are based on Latin *saponis* and *sapo* (first used by Pliny, A.D. 23–79). Soap is *sapone* in Italian, *savon* in French, *jabón* in Spanish, and *sabão* in Portuguese. Greek is *saponos*. One suggestion is that Europeans learned the words and soap-making process from the Tartars, and that may be correct. Still, all these words are related to Latin *sebum*, tallow. After all, there is no soap without oils and fats.

People in the New World had abundant wood ashes, but they were always short on fats. There were few native fatty animals in the Americas, and it was always a struggle to get enough in their diets to survive. Bears (*Ursus americanus*) and opossums (*Didelphis virginiana*) were among the few good sources of fats. To give an idea of the change in importance of fat sources, the Cherokee, before Europeans, called the opossum *si'-qua*. After the pig (*Sus scrofa*) was introduced, it became *si'-qua* and the opossum *si-quu:-tes-ts'* (smiling pig) (Mooney 1885–1886). A similar shift took place in Mikasuki, Choctaw (*shuhka*, pig, and *shukata*, from *shuhka*, opossum, and *hata*, white), and Creek (see also *Cyperus* and *Sagittaria*).

Indigenous Americans were aware of soapy plants. In Florida, certain trees were called soap-berry (Florida to Panama) by the Europeans. This tree, *Sapindus saponaria* (from Latin *saponis*, soap), was Indian soap. *Sapindus* grows from southern Florida through the Bahamas, the West Indies, and in Mexico (Sinaloa to Veracruz) south to Peru and Argentina. Depending on the definition used, there are either two other species or two variants of *S. saponaria*. A kind lacking winged rachises is *S. marginatus*; it grows in northern Florida and nearby adjacent states. The third is *S. drummondii*, or *S. saponaria* var. *drummondii*, which grows from Kansas and Louisiana to Arizona and northern Mexico. Ethnobotanically all may be considered together.

Gonzalo Fernández de Oviedo y Valdés was probably the first European to record these trees in 1535. He called the seeds *cuentas de xabón* (counting soap, Mexico). That name records two of the uses that Americans had for the seeds, counting, perhaps in beads (as necklaces and rosaries), and soap. The first idea persists today in *palo de cuentas* (counting tree, Oaxaca). Osage say it is *wa-non-p'in-hi* (*wa-non-p'in*, necklace, *hi*, tree). In Florida use in necklaces is recorded in *ahina:ka:sí* (bead tree, Mikasuki) and in Creek *tokona:wá* (*eto*, tree, *konawv*, bead). The Biloxi of Louisiana said *aya'yiñk udi'* (*ayan*, tree, *yiñki'*, small, *udi'*, acorn).

The soapy trait was not confined to washing, but the saponins were also used to catch fish. Other people fishing with the seeds say *jequitinhaçu* [*jequitiguaçu*] (*ye'kei*, basket for fishing, *tinha*, false, *açu*, big, Tupí, Brazil). A Guaraní name *yequiti* (*ye'kei*, basket for fishing) is used in Argentina. Surely, *salta-martim* (jumping-kingfisher, Brazil) refers to catching fish. Is it possible that fishing is also the reference in *devanador* (*devanar*, to spool, wind on spool, Veracruz)?

However, people from the Aztecs to the Europeans noted the soapy traits for washing. To the Mexicans, seeds were *amolli* [*amole*, *yamolli*, *yamole*] (soap, Náhuatl). The Aztec word was so quickly adopted into Spanish that people were soon calling the fruits *amole de bolita* (soap balls, Mexico) or *amolillo* (little soapy one, Sonora). Any relationship between soap and the name *tehuistle* [*tehuztle*, *tehuixtle*, *tehuiztl*, *tehoizli*] (sharp rock, Náhuatl) is no longer apparent. The Zapotecs say *amole bibi* (*amole*, soap, Náhuatl, *bibi*, fruit, Oaxaca), *bibi* [*pibi*, *pipé*, *pipi*, *pipal*, *pepe*, *pepo*] (*bi*, fruit, Oaxaca), and *yaga bia* [*piaa*] (*yaga*, tree, *piaa*, fruit, Oaxaca). The Mixe use *pipe*, a loanword from their Zapotec neighbors.

While a variety of names are known for other people, translations are lacking. Many are perhaps simple terms. *Chorote* (Dominican Republic) may be from Taino. In Mexico and Central America trees are *güiril* [*guiril*, *gualulo*, *guayul*, *hualul*, *hualule*, *huaya*, *huayul*, *huiril*] (Oaxaca, Guatemala, Belize), *coyul* (Mexico), *cuyus* (Nicaragua), *choloco* [*cholulo*] (fruit), *jutuhui* (Guajillo, Sonora), *ma-mu-jo* [*ma-mu-ho*] (Mexico), *morkowekuak* (Cuna), *pacón* [*pacun*, *pacum*] (Guatemala, El Salvador, Honduras), *snotpu'u* (Mexico), *tubchi* [*tupchi*] (Mayo, Sonora), *tzatzupu* (Mexico), and *ximbi'p* (Mexico). South Americans say *chumbimbo* [*chambimbe*, *chumbino*] (Colombia), *marikuru* (Arawak?), *micchu* (Colombia), *jisotoubo* (Bolivia), *para-para* [*paraparo*] (Venezuela), *quillay* (Mopori, Chile), and *sulluco* (Quechua, Peru).

Other Spanish words are more widely used. Most commonly used is *jaboncillo* [*jaboncelle*, *jaboncillal*, *jabonera*] (little soapy one, Sonora, Nuevo León, San Luis Potosí, Durango, Tamaulipas, Veracruz, Yucatán, Guatemala, Nicaragua, Costa Rica, Cuba, Puerto Rico, Panama, Colombia). In Argentina *Sapindus* is *palo jabón* (soap tree). Even the Maya mix Spanish and Maya as *jabón-ché* (soap tree, Mexico, Belize). Sometimes, people say *chirrión* (squeaky one, Mexico) or *luci* (*lucer*, to brighten, shine, Mexico), to note how clean things become.

In French colonies, people call the trees an *arbre savon* (soap tree, French Antilles), *bois de savon* (soap tree, French Antilles), *bois de savonette* (soap tree, French Antilles), *bois savonette* [*bwa savonette*] (soap tree, Haiti, French Antilles), *savonettier* (soap tree, Guadeloupe), or *savonnier* (soap tree, Central America, USA). Sometimes, they use terms like *bois maousseux* (foaming tree, Guadeloupe), *savonette montagne* (wild soap, Guadeloupe), *savonette mousseuse* (foaming soap, Guadeloupe), *savonette pays* (wild soap, Haiti), or *savonnier des antilles* (Antilles soap, Lesser Antilles).

To Brazilians trees are *saboeiro* (soap tree), *saboneteiro* (soap tree, Pernambuco), or *sabãozinho* (little soap), and *fruta-de-sabão* are fruits. Sometimes they just say *sabonete* (soap, Ceará). Apparently, the Brazilian army had soldiers use the fruits, and that is why they are called *sabão de soldado* (soldier's soap) or *sabonete de soldado* (soldier's soap). Further indication of the wild source is *sabão de macaco* (monkey's soap).

In former Dutch colonies, the trees are *savonetapel* (table soap, Curaçao) or *sopo sirie* (soap seed, Sranan, Suriname). Germans call the tree *Seifenbaum* (soap-tree).

English names are surprisingly varied, probably indicating more uses than some other plants. The trees are Florida soapberry (USA), Mexican soapberry (Texas to Belize), mountain cherry (Belize), southern soapberry (USA), sumac-leaved soapberry (USA), winged [wing-leaf] soapberry (USA, Central America, South America), and West Indian soapberry (USA). A bit more imagination goes into the names soap-nuts (English) and soap-seed [soapseed, soap seed] tree (Belize), but not into soap-tree (Belize).

Some think they should be called false dogwood (USA), although the similarity escapes me. The comparison of seeds to marbles, in black nicker tree, makes more sense. Wild China-tree (USA) notes that the plants, fruits, and seeds resemble those in chinaberry, *Melia azedrach*. Several of the other comparisons are clear but some are obtuse. They are correctly *arbolio* (little tree, Sonora), and their seeds do resemble miniature balls for *boliche* (bowling, Sonora, Peru). Older mention of the black seeds is in *bois de merle* (blackbird tree, French Antilles) and *sibul* [*subul*, *zubul*, *sihom*] (*subul*, black bird, Maya, Yucatán, Belize).

Since the seeds are poisonous, one can see why they are *graine canique* (dog seed, Haiti) or maybe used as a *jurupe* (*jurar*, to swear, curse, Ecuador). Perhaps the same ideas are part of *mata de chivo* (goat bush, Dominican Republic), *mata muchacho* (boy killer, Sonora), *maté negro* [seeds] (black tea), and *palo amargo* (bitter tree, Dominican Republic). Surely, “seahone té” (Belize) is a corruption of *sabón té* (soap tea). Those last four names are surely associated with uses in teas as a febrifuge and tonic, and to treat kidney problems (Standley 1920–1926, Duke 1972, Morton 1981). Since the fruit contains up to 37% saponin, the names may also be connected with treating rheumatism, gout, tumors, and swellings (Takagi et al. 1980, Morton 1981). *Sapindus* has acetylated triterpene saponins (Kanchanapoom et al. 2001) that are known to be antimicrobial (Tamura et al. 2001) and that have even been used to detoxify snake venom (Castro et al. 1999). The compounds also inhibit tumor cells (Meyer-A. et al. 2001).

The bark is white, so that may have led to *palo blanco* (white tree, Chihuahua). Use of the wood may have given *zapotero* (shoe-maker). Comparisons no longer clear are *casita* (little house, Argentina, Paraguay), *chocho* [*choco*] (childish old man, Colombia), *limoncillo* (little lemon, Panama), and *palo de voladillo* (flying tree, Mexico). Maybe these names are associated with wood being used as fuel, treating wounds, or powdered seeds used as an insecticide (Standley 1920–1926, Duke 1972, Morton 1981, Dhar et al. 1996).

It is always surprising how we humans recycle ideas. Americans knew that *Sapindus* was a good soap for thousands of years. Still, in 2000, the idea was resurrected to win the Coca-Cola Award in Ecoefficiency. A student at the Universidad Nacional Agraria La Molina, in Lima, Peru, took the prize with “*Obtencion de un detergente biodegradable y de un material de construccion a partir del boliche (Sapindus saponaria)*” (Extraction of a biodegradable detergent and construction material from *boliche*).

What is old is new.

### Sarracenia

(Named by Linnaeus to commemorate Michel Sarrasin de l’Etang, 1659–1734, the Court Physician of Quebec)

***Sarracenia*.** *Sarracenia flava* (left).  
*Sarracenia purpurea* (right). Both  
 from Britton and Brown 1897.

***Sarracenia flava* (yellow)**

biscuits (probably a reference to the frisbee-shaped stigmas)  
 bonnet lily  
 [Eve's, water]-cup (tubular leaves hold water, and dead insects)  
 [umbrella-topped] flycatcher (used by Porcher 1863); flytrap  
 [trumpet, yellow-flowered] pitcher plant (first applied to *Nepenthes* of  
 the Old World by 1835, and then to *Sarracenia* by 1857)  
 sidesaddle-flower (used by Porcher 1863)  
 [golden, yellow, southern] trumpet(s); trumpet-leaf [trumpet leaf] (in  
 use by 1884); trumpet plant (apparently more recent than trumpet-leaf; not  
 in the OED 1971); huntsman's horn  
 watches (see *S. purpurea* for derivation)

***Sarracenia minor* (smaller)**

hooded pitcher plant  
 [spotted] side-saddle plant  
 smallpox plant  
 trumpet plant (Florida Panhandle)

***Sarracenia purpurea* (purple)**

*ayekitas* [*ayikitas*, *ayikicas*] (little frog pants, Cree)  
*bleuets* (little blue one, Quebec)  
 bog-bugle (South)  
*cochons de pelé* (bald pigs, Quebec); *petits cochons* (little pigs,  
 Quebec)  
 [Adam's, Eve's, fever, forefather's, huntsman's, Indian, meadow,  
 water]-cup (Maine, Massachusetts, New Brunswick)  
 devil's-boot (South)  
 flytrap (South Carolina)

- fox-glove [foxglove] (Maine)
- frog-bonnet (South)
- herbe-crapaud* (toad herb, Quebec)
- Indian jug [pipe, teakettle] (Newfoundland)
- kokokoo* 'manasin (owl's shoes, Potawatomi)
- [Adam's, forefather's, Indian]-pitcher (Maine, Massachusetts, New Brunswick); [common, northern, purple] pitcher-plant
- sabot* ([horse] hoof, French)
- sidesaddle-flower (Mark Catesby wrote in 1738 that "the under part of the flower is somewhat the seat of a side-saddle, from which in Virginia it has received its name")
- skunk-cabbage (usually used for *Symplocarpous foetidus*, Araceae, Minnesota)
- smallpox-plant (from medicinal use)
- St. Jacob's-dipper (reported by Grace Greylock Niles in 1904, in the book *Bog-Trotting for Orchids*, Vermont)
- ts'eli tili* (frog pail, Chipewyan, Canada)
- [dumb] watches (reported by Grace Greylock Niles in 1904, "because children playing with the hard shells of the stigmas...call them watches," New Jersey, Vermont)
- whippoorwill's-boots [-shoes] (Maine, Pennsylvania)

The standard explanation for the dedication of the genus *Sarracenia* is that Michel Sarracin de l'Etang (1659–1734), physician at the Court of Quebec, sent the first specimens of at least *S. purpurea* to Europe (Fernald 1950, Quattrocchi 1999). However, Diggs et al. (1999) were not caught in that trap. They wrote simply that the name was dedicated to Sarracin. Indeed, a survey of the synonyms published by Linnaeus ([1753] 1957) makes it clear that both *S. flava* and *S. purpurea* were known in Europe before Sarracin was born. Plants now called *S. flava* were known to Matias de l'Obel before 1570, and those now called *S. purpurea* were discussed by Gaspar Bauhin in 1623.

Linnaeus ([1753] 1957) listed only those two species. Subsequently, more have been discovered to bring the total to eight, all endemic to eastern North America (Mabberley 1997). The hybrids are difficult to recognize and people tend to confuse them with other species. Kartesz (1994) recognized 17 with formal names.

Although Hocking (1997) recorded use of three of the species in Florida, both Vogel (1970) and Moerman (1998) found only *S. purpurea* in the records of indigenous tribes. This sparse record perhaps reflects loss of information rather than lack of use. Regardless, *S. purpurea* was used by at least the Algonquin, Cherokee, Cree, Iroquois, Malecite, Menomini, Micmac, Montagnais, Ojibwa, Penobscot, and Potawatomi (Smith 1933, Core 1967, Vogel 1970, Moerman 1998).

Core (1967) noted that the people of the southern Appalachians, typically the Cherokee in his study, used the leaves as drinking cups when on trips. That same use was found among the Potawatomi, particularly when they were in the swamps where these plants grew (Smith 1933). Cree and Ojibwa children used the leaves as toy kettles.

The most widespread application of *S. purpurea* was as medicine. The Algonquin used it to ease the pain of childbirth and to treat urinary problems (diuretic). The Cree took it

to remedy the sickness associated with absence of a menstrual period, to prevent sickness after childbirth, to help expel the afterbirth, to relieve lower back pain, and to treat venereal disease. The Iroquois used *S. purpurea* as "Basket Medicine," to alleviate thirst, chills, fever, liver problems and whooping cough, as a "love medicine," and as lacrosse medicine (presumably to make them play better). The Malecite, Micmac, and Penobscot took an infusion for tuberculosis and other pulmonary problems. The Menomini thought the plants were used by sorcerers. The Micmac used *S. purpurea* to relieve kidney problems and sore throat. The Montagnais treated smallpox with it. The Ojibwa and Potawatomi used the herb to ease the pain of childbirth (Smith 1933).

Although the indigenous people were well acquainted with the medical aspects of *S. purpurea*, settlers were not always privy to that information. John Josselyn wrote in 1672, "I wonder where the knowledge of this plant has slept all the while, i.e., above forty years" after he learned about its properties. He continued, "It is excellent for all manner of fluxes."

Millspaugh (1892) was more guarded about pitcher-plants. He was involved in a debate about whether or not the plants were effective in treating smallpox. According to him, the people of north-eastern Canada (Montagnais?) considered *S. purpurea* a specific in treating that malady. An incident is recounted where everyone was alarmed during an outbreak of smallpox in 1861. After the arrival of an old indigenous woman, "the alarm had greatly diminished," because she went among the ill and treated them with an infusion of *Sarracenia* roots.

A contrary opinion was proffered by another physician. He said that, "This medicine was thoroughly tested...in the spring of 1864 at the Small-pox Hospital at Claremont, in Alexandria, Va., for a period of several weeks...and proved to be without any curative powers in this disease." Offering an alternate view, Millspaugh (1892) quoted from another person who added that, not only did the plant save his brother's life, "but its use also appears to wholly obviate the unsightly pitting common to the disease." He then added, "if it is extracted and dried at the proper season."

Based on a study by Porcher of *S. flava* published in 1849, Millspaugh (1892) thought that *S. purpurea* caused "diuresis, moderate catharsis, and gastric excitation, as well as an increased and irregular heart's action, and congestion of the head." His concluding remark was that an experiment in Europe "corroborates the aborigine's use of the drug, and adds one more proof to the many that are tending to reveal the fact that our American native practice was essentially correct." Hocking (1997) concluded that *S. purpurea* was useful as a "stimulant, tonic, laxative, in dysentery, diuretic, diaphoretic, smallpox, pain."

Porcher (1863) wrote of *S. flava*: "We are informed by several gentlemen of this state that these plants are used in dyspepsia with great service. The roots are undoubtedly possessed of bitter, tonic, and stomachic properties; and we are credibly assured of a number of cases in which relief has been experienced from them. The taste is disagreeable to those using them for the first time, but eventually it becomes pleasant, as we have ourselves experienced. An infusion might serve as a useful substitute for bitters."

He continues: "It is supposed by many to relieve most of the distressing symptoms of this affection [dyspepsia], among which may be cited: gastralgia, pyrosis, acidity, and the general feeling of malaise, so frequently attendant upon it. In some it induces considerable diuresis, and in others soreness of the mouth. In experiments made upon my

own person, to ascertain its physiological effects upon a healthy individual, it exhibited a tonic, stimulating influence upon the digestive organs, producing some cerebral disturbance, when persisted in.” Chemical examination by a colleague showed that “it contains besides lignin, coloring matter, and traces of a resinous body, an acid, or an acid salt, and also an astringent property, due neither to tannic nor gallic acid, and a salt of some alkaloid, related perhaps to cinchonia, which, should it prove new, may be called sarracenin. ...A bit of the fresh or dried root of either species may be chewed, and the juice swallowed, during the day before each meal; it may be given powdered in the form of pill, with a little rhubarb if necessary, or a tincture may be made by pouring a pint of brandy over several ounces of the root, of which half an ounce, diluted, may be taken three times a day. I have lately had cases reported to me, of its marked success in the relief of chronic diarrhoea and dysentery, and I am pleased to learn that it is now widely used in other portions of this state, and in Georgia, with very general approbation.”

Hocking (1997) stated that *S. flava* had an astringent rhizome and that it had been used as a demulcent in dyspepsia, pyrosis, diarrhea, analgesic. A tincture is tonic, and stomachic in gastralgia. He found that it had been used as a food called “gator tator,” and had been an ingredient in moonshine. Unfortunately, he did not give more details on the last two uses.

Hocking (1997) wrote that *S. minor* was formerly used to treat smallpox, skin rash, and eruptions. Because of its spots, he considered that an application of the Doctrine of Signatures. That philosophy certainly was not why people in the Panhandle used it as a remedy for coughs and indigestion, and to stop vomiting (Murphee 1965).

Modern chemical studies have confirmed that *Sarracenia* contains the alkaloid serracenine, plus serapine (anesthetic principle), anthocyanidins, betasitosterol and alpha-amyrin, the unusual enol diacetel monoterpene sarracenin, the triterpene betulinaldehyde, and volatiles (Miles et al. 1975, 1976, Bhattacharyya et al. 1976, Miles and Kokpol 1976, Hocking 1997, Newman et al. 2000, Sheridan and Griesbach 2001). Lupeol showed antitumor activity (Miles et al. 1974, Miles and Kokpol 1976). There is also the insect paralyzing agent coniine (Mody et al. 1976). Duke et al. (2002) wrote of *S. purpurea*, “If it really contains coniine...it should be avoided.”

### *Sassafras*

(In naming this genus, C.G.D.Nees von Esenbeck, 1776–1858, is said to have applied an aboriginal name *sasafràs* used by the French in Florida)

#### *Sassafras albidum* (white)

ague tree (from its use in treating fevers, of malarial and other origins)

*cahkanî* [*cakani*] (Mikasuki); *chihkafo* [*chihkafo*] (Alabama); *cihkafo* (Koasati)

cinnamon wood (Monardes first compared it to *Cinnamomum verum* and others in 1569)

***Sassafras albidum*.** From Sargent  
1905.

*Fieberbaum* (fever tree, German); *fiewerbaum* (Pennsylvania Dutch)  
*filé [gumbo]* (powdered sassafras leaves used to thicken and season soups, stews, and gumbos; the past participle of French *filer*, to spin thread, from its effect when added to hot liquids, from Old French, Louisiana)

*gehachgamápuek* (Delaware); *pawquanemekysee* (Shawnee, cf. Edgar 1891)

*hvsh* (*akshih*, root, Choctaw; compare with *kombo ashish* and *kafe ashish* below)

*kafe ashish* (*kafe*, coffee, *akshih*, root, Choctaw, which incorporates the English loan-word; this is the name Bushnell 1909 gave for only the medicine with “The roots are boiled in water and the extract is drunk ‘to thin the blood’”)

*kafi*’ (the same word is used for alien coffee, *Coffea*, although it is sometimes pronounced and spelled *kaafi*’, Chickasaw); *kafi [iti kafi]* (Choctaw; the same word, *kafi*, is used for *Diospyros*, which see)

*kombo ashish* (*kombo*, sassafras, *akshih*, root, Choctaw; the word “gumbo,” as in French *filé gumbo*, the seasoning now attributed to the Acadians of Louisiana, is from Choctaw; this term was in use in 1909 when Bushnell worked among the people of Bayou Lacombe; however, Byington et al. 1915 did not include *kombo*; there is, however, the well-attested Chickasaw word *kombo*’)

*ku’stapi?* (Catawba)

*kunstutsi* [*ka:-n-s-ta-tsi*’, *kúnstú’tsi*, *kansdaji*] (Cherokee; a gap in the Great Smoky range, about the head of Noland Creek, on the line between North Carolina and Sevier County, Tennessee was called *Kunstutsi’yi* “Sassafras place”)

*pauame* (Timucua name given by Monardes in 1569)

*salep* [*saloop*] (archaically, a hot drink, sometimes used medicinally, made from salep, sassafras, or similar aromatic herbs; derived from Ottoman Turkish *slep*, from Arabic *salab*, a kind of orchid) sassafras [*laurel*] (Monardes in 1569 said the French Huguenot he met called the tree *sassafras*, and the Spanish from Florida corrupted that to *sassafragia*;

maybe that is how the version originated that the name was from Latin *saxifraga*, a variant of *herba saxifraga*, a medicinal herb now applied to a completely different plant in the Saxifragaceae; however, even Monardes's story does not account for a totally distinct Timucua name, *pauame*, for the tree); sassafras (fide Small 1933); saxifras (Strachey in 1612); white sassafras (this English name reflects an observation also made by the Seminoles; they recognized two "kinds" of sassafras; *cahkankitisci*, red sassafras, and *cahkansopatfi*, gray, or *cahkanhátki*, white; the root bark is red, and the stem bark gray, hence the distinction)

*shi-kee* (Osage; *she'-ke* is a rattlesnake, perhaps there is confusion)

smelling-stick

*swanággerachs* (it is not clear if this is an indigenous name, or an attempt by these people to pronounce "sassafras," Onondaga)

*weso* [*wéso*, *we:so*, *we-sho*, *wi:so*, *wi'su*] (Creek, Muskogee)

*winachk* [*wink'nachk*] (*wink'*, pleasant [taste], *wonáchk*, tree bark, Delaware); *winauk* (sticky tree, Powhatan, Virginia)

*Sassafras* is a genus of three species, one endemic to eastern North America, and two in China and Taiwan (Mabberley 1997, Peng 2000). *Sassafras* was discovered by the Spanish in Florida in 1528, although the OED (1971) gives no source for that information. Core (1967) was in error when he wrote that the tree was "discovered in 1602 by Bartholomew Gosnold." At least Monardes in 1569 (Frampton [1577] 1925), Harriot (1590), and Gerarde ([1597] 1975) preceded that 1602 date.

The first newcomers to the New World had no idea that this new tree would become such an economic resource for the Old World. Sassafras literally launched flotillas of ships to Florida, and made patrons and financiers in Europe incredibly wealthy. The demand was such in 1625 for the Virginia Company to "bestowe their moneyes...upon two comodities onely, Tobacco and Sassafras matters of present profit" (Vogel 1970).

As John Uri Lloyd wrote in the late 1800s, "this tree at one time created greater interest in the Old World than any other American product, not excepting tobacco" (Vogel 1970). As a medicine, sassafras eclipsed *lignum vitae* (*Guajacum sanctum*) and held that position for years. Harriot ([1590] 1972) reflected the opinion of the times when he wrote that sassafras was "farre better and of more uses than the wood which is called *Guaiacum*, or *Lignum Vitae*." The bark of sassafras was listed in the *Pharmacopoeia Londinensis* in 1618. Later, the dried root bark was in the U.S. Pharmacopoeia, 1820–1926, and the National Formulary, 1955–1965; sassafras oil was in the U.S. Pharmacopoeia, 1820–1955, and in the National Formulary, 1955–1965; and safrole was in the U.S. Pharmacopoeia 1905–1916 (Vogel 1970).

Authors of the Oxford English Dictionary (OED 1971) dismiss the story of sassafras discovery as medicine as told in 1569 by Nicholas Monardes (1493–1588). The OED says, "The Spanish writer Monardes...regards the Sp[anish] name as adopted from Fr[ench], which seems unlikely." These bibliophiles were relying too much on etymology and too little on history. Vogel (1970) understood Monardes correctly. Monardes erred largely in believing that medicine from sassafras cured such a remarkable variety of maladies.

The history of a brief French presence in Florida is well known and documented (cf. Milanich and Milbrath 1989). Knowledge of French Huguenot René de Laudonnière's establishment at Fort Caroline on the River May (now the St. Johns River) reached Spain at the end of March 1565. That date was after Pedro Menéndez de Avilés's royal contract had been signed making him *adelantado* and requiring him to explore a Florida extending from the present Florida Panhandle around the Florida Keys thence north to Newfoundland. After establishing a settlement at St. Augustine in September 1565, he captured Fort Caroline. He then renamed that fort San Mateo because he captured it on St. Matthew's Day in 1565 (Bloodworth and Morris 1978). Next, he killed the French leader, Jean Ribaut, and many of his followers on the beaches of Matanzas, south of St. Augustine. However, some of the French were retained as captives.

Monardes's version follows that history particularly well. First, he told of a Frenchman teaching him about the tree and establishes the time. Monardes wrote in 1569: "It maie be three yeeres paste, that I had knowledge of this Tree, and a Frenche manne whiche had been in thos partes, shewed me a peece of it, and tolde me merveiles of his vertues. ... He tolde me that the Frenchemen, which had been in the Florida at that tyme, when thei came into those partes, thei had been sicke the moste of theim, of greevous and variable deseases, and that the Indians did shewe them this Tree, and the maner how thei should use it." That would make the year that Monardes met the Frenchman 1566, the year after Menéndez expelled the Huguenot colony.

Later Monardes continued, "After that the Frenche menne were destroyed, our Spaniards did beginne to waxe sicke, as the Frenche menne had dooen, and some whiche remaine of them, did shewe it [sassafras] to our Spaniards." This is a highly synoptic version of the massacre that gave modern Florida the place name "Matanzas."

Still later Monardes noted that Pedro Menéndez (rendered almost unrecognizable as "Peter Mellendis" by Frampton [1577] 1925) "brought with hym in common this woode of the Sassafras." Monardes wrote that Menéndez saw many of his men healed with sassafras.

Monardes goes on to say, "The Tree groweth in some partes of the Florida, and doeth not grow in others." He specifically mentioned it growing at the port of St. Elen [San Helena, Leon County] and the port of St. Mathew [San Mateo, Duval County] "and not in others." Maps in Little (1978) and Wunderlin and Hanson (2002) confirm sassafras presence in both places. In Monardes's time, the interior of the peninsula was unknown and he had no way of knowing that the tree extended inland farther south.

According to Vogel (1970), sassafras "was used in some way by virtually all Indians living in its range." Moerman (1998) listed the following tribes as using sassafras: the Cherokee, Choctaw, Creek, Delaware, Houma, Iroquois, Koasati, Mohegan, Nanticoke, Rappahannock, Ojibwa, and Seminole. Other sources add Alabama, Catawba, Kickapoo, Osage, Powhatan, Quapaw, Carolina Algonquians, and Timucua (Frampton [1577] 1925, Harriot [1590] 1972, Vogel 1970, Howard 1984). Yanovsky (1936) said it was used by tribes in the eastern and southern states.

We know from Monardes that the Timucua "doeth use to put them [sassafras leaves] beaten or stamped upon bruses, or of any manne beaten with drie bloews, and beeyng drie, thei are used in Medicinable thynges" (Frampton [1577] 1925). The Creeks boiled the roots with an unidentified grass (maybe *Andropogon*, which see) for patients with bowel and stomach pains accompanied by vomiting (Vogel 1970). Some of the Creeks

also mixed sassafras with devil's shoestring (*Tephrosia virginiana*) to treat bladder problems and coughs (Swanton 1928a). The Seminoles visited by Greenlee in the 1940s used sassafras to treat coughing, gallstones, and bladder pain (Vogel 1970).

Sturtevant (1955) recorded the Miccosukees on the Big Cypress Reservation, well south of the natural range of sassafras, still using the trees. In part, their uses reflect their Creek heritage as some of the same maladies are recognized by their relatives (Swanton 1928a, Howard 1984). The Miccosukee used sassafras to treat "Cat Sickness" (nausea), "Cow Sickness" (chest pain, digestive upsets, diarrhea), "Dog Sickness" (appetite loss, drooling), "Horse Sickness" (nausea, constipation, blocked urination), "Monkey Sickness" (fever, itch, enlarged eyes), "Mythical Wolf Sickness," "Opossum Sickness" (appetite loss, drooling), "Otter Sickness" (diarrhea, vomiting), "Raccoon Sickness" (diarrhea), "Wolf Ghost Sickness" (diarrhea, painful defecation), and "Wolf Sickness" (vomiting, stomach pain, diarrhea, frequent urination). These are only the "major" uses and they had a number of other remedies involving sassafras (Sturtevant 1955).

Several other Muskogean tribes used sassafras. The Alabama made a tea of roots that was drunk to relieve stomach trouble or pain, used it against pneumonia, and considered it to be "good for the blood" (Howard 1984). Sometimes the Alabama made a gumbo soup to relieve the same problems (Howard 1984). Charles S. Sargent, in his *Manual of the Trees of North America* (1905), recorded that the Choctaw still were preparing powdered leaves to be sold for making *filé gumbo*. They were still adding those leaves to their soups when visited by Bushnell (1909). The Alabama boiled sassafras root with the head bones of a hog to make a dish they call *yakchi*.

The Houma used a decoction of fresh or dried roots to try curing measles and scarlet fever (Speck 1941). The Koasati made a poultice of mashed leaves to relieve bee stings (Taylor 1940).

The Choctaw made a tea "to thin the blood" (Bushnell 1909). A similar tea was used virtually throughout the range of the plants by indigenous tribes. In addition to the medicinal use, settlers of varying ethnic backgrounds quickly adopted the tea as a beverage or in more complex mixtures (Murphee 1965, Vogel 1970). Settlers added sassafras to pine, molasses, and spruce beer, and it was a critical component in root beer (Vogel 1970).

Eventually, researchers began looking at safrole, the best-known active ingredient in sassafras. Laboratory studies on mice showed that this compound, which is chemically related to myristicin and asarone, was both carcinogenic and hepatotoxic (Lewis and Elvin-Lewis 1977). Safrole was banned by the Federal Department of Agriculture (Foster and Duke 1990). Use of sassafras is prohibited by the European Union (Mabberley 1997). One report says that levels of 0.66 mg/kg may be hazardous to humans, and a cup of tea contains nearly five times that much (Newell et al. 1996). Like Duke et al. (2002), I prefer another perspective—sassafras tea is 1/13th as carcinogenic as a beer.

### ***Saururus*: Lizard's Tail**

(From Greek *sauros*, lizard, *oura*, tail)

*Saururus cernuus*. a. Top portion of plant, b. Portion of lower stem showing adventitious roots, c. Flower, showing carpels united at the base only (no calyx or corolla), d. Fruit, with persistent stamens, e. Carpels breaking apart. Drawn by Vivian Frazier. From Correll and Correll 1972.

The odor is one of the things still fresh in my memory—apart from wondering if alligators really were dangerous—from the first time I waded thigh-deep into the Fakahatchee Strand in 1970. The large, green herbs in a pond gave off the scent of licorice and mint as I walked through them. All who have waded through swamps in Florida will have come across spots where there are acres of lizard's tail (*Saururus cernuus*). Even if they do not notice the rich green heart-shaped leaves, or the stems reaching waist high, most people, like me, note the plants. Once the stems and leaves are bruised by your passing, they release a pleasant spicy fragrance that demands attention. Yet, the species apparently remained unknown to Europeans until British botanist Leonard Plukenet published the first illustration in 1696 under the name *Serpentaria repens, floribus stamineis spicatis* (prostrate snakeroot, flowers with stamens in spikes). That was fully 200 years after Europeans arrived in the Americas.

Even then, professor of economic botany Peter Kalm did not mention the species from his visit to New England and nearby Canada in the 1740s (Kalm [1753–1761] 1972). Nor did that inveterate explorer of wetlands William Bartram remark on the plants in his book

of travels through the southeast in the 1760s (Bartram [1791] 1958). Why this prominent wetland plant was so late in becoming known to Old World biologists remains something of a mystery. Given the importance of *Saururus* among the indigenous groups, it is tempting to speculate that these people withheld information on a sacred plant.

In 1739, Dutch botanist Jan Fredrik Gronovius's named the genus *Saururus*, based on a specimen that country clerk and amateur botanist John Clayton had sent from Virginia. If Gronovius had ever seen the living plants, he surely would have called the genus something else. Only dead, brown dried specimens are reminiscent of the namesake. Living plants have startling, if not spectacular, white flower stalks in the spring wetlands that contrast strongly with the dark green of the foliage. Linnaeus, who retained Gronovius's name for the plants, also gave *Saururus* the species name *cernuus* (nodding), to note a trait of the flower cluster.

There are only two species of *Saururus*, *S. cernuus* in North America, and *S. chinensis* in Asia (Mabberley 1997). The family (Saururaceae) contains only four genera, and like *Saururus* it is divided between south-eastern Asia and southern North America. All are aromatic and medicinal.

In English the dominant common name has been lizard('s)-tail since about 1753. Other English names include water-dragon, swamp lily, black sarsparilla, and breastweed. There is some evidence that the last four are more recently applied. Spanish speakers call it *yerba mansa* (tame herb). The scientific name has simply been translated to create common names in German, *Molcheschwanz* (*Molch*, lizard, *schwach*, weak), and French, *saururé penché* (*saururé*, lizard, *penché*, nodding) or *queue de lézard*. However, there are indigenous American names for the plants, including *ishuna ignone* (*iskuna*, guts, *ik*, not, *nuna*, ripe, Choctaw), *oyihiliswa* (*owe*, widow, *heleswv*, medicine) in Creek, and *yahkakayikcí* in Mikasuki (widow or widower medicine).

Foliage and roots of *Saururus* were widely used by the Americans. For example, we know that people like the Cherokee of the Carolinas, the Choctaw of Louisiana, the Ojibwa of Minnesota, and the Seminoles of Florida all used the plants. On the other hand, it is not among the species enumerated as used by the people of the entire Missouri River region.

The Choctaw and other Americans used the plants in poultices for wounds, for inflamed breasts, and inflammations in general (Bushnell 1909). Treatment of skin problems was the most widespread type of use recorded, including treatment of spider bites. Tea was made of the whole plant to treat illness associated with fever and aching, rheumatism, and stomach ailments. Generally, the medicine from *Saururus* was considered good for pleurisy (inflammation of the plura or sacs around the lungs), rheumatism, as an emetic, an antispasmodic, an astringent, a sedative, an emollient, and as a mild tranquilizer.

In the 1790s French botanist André Michaux, living in Charleston, South Carolina, wrote that usage was common among residents. Furthermore, he recorded: "*Le Saururus cernuus est reconnu très bon remède pour meurer les palyes qui viennent a suppuration et en diminuer l'inflammation. On fait bouillir les recines ou les broye, on y ajoute un peu de farine de froment pour en fair un cataplasme*" (*Saururus cernuus* is known as a very good remedy for sores and inflammations. The roots being ground or boiled, some wheat flour added, are then used as a poultice). That segment was quoted by Sturtevant (1955) from Michaux's journal of 1785 to 1796.

Not only is the Florida native medicinal, but members of this small family are used throughout the world. The Asian *S. chinensis* is also used to treat inflammation and as a sedative. Similarly, the related *Anemopsis* of the southwestern United States and adjacent Mexico has those same uses (Moore 1989, Kay 1996). Like the Florida plants, those in the west are called lizard's tail in English and *yerba mansa*, *yerba del mansa*, or *yerba el mansa* (tame herb or herb of the tame one) in Spanish. In addition to the similar uses, that species has a variety of names recorded by various people, including the Apache, Opata, Pima, Mayo, Yaqui, Papai, and Seri.

It is probably safe to say about *Saururus*, as has been said about *Anemopsis*, that "everybody who has lived where *yerba mansa* grows has used it as a medicine" (Moore 1989). Widespread usage for poultices on external lesions and its emetic nature make the statement likely.

Possible infection from wounds was a constant problem before the discovery of modern antibiotics. For example, ignorance of ways to fight infections probably caused at least as many deaths during the Civil War as direct battles. Any plant that provided even marginal protection from this danger was sought by people throughout the world.

The aristolactam analogues cepharanone B and sauristolactam are not only antiseptic but also antitumor (Rao and Rao 1990). In addition, *S. cernuus* contains the antioxidant dehydrogeranylgeraniol and the sedative manassantin A (Rao et al. 1987, Rao and Reddy 1990, Rao et al. 1990, Rajbhandari et al. 2001). Each genus (*Anemopsis*, *Houttuynia*, *Saururus*) has its own characteristic essential oil, and these compounds inhibit several types of viruses, including herpes simplex, influenza, and human immunodeficiency (Childs and Cole 1965, Acharya and Chaubal 1968, Sanvordeker and Chaubal 1969, Tutupalli and Chaubal 1975, Tutupalli et al. 1975, Hayashi et al. 1995). The Asian *S. chinensis* also has been shown to fight infections, and provide liver protection because of its diastereomeric lignans, flavonoids, furanoditerpenes, saucernetilignans, and sesquiligans (Xu and Xu 1986, Sung et al. 2000, Sung and Kim 2000, Ahn et al. 2001, Sung et al. 2001, Ma and Ruan 2001, Hwang et al. 2002).

Emetics also were an essential part of the cultures of the people living in the southeastern United States, especially those whose languages were allied with Creek (Muskogean language group). There was a custom among all these groups of observing the *posketv* [*poskita*] (to fast, Creek). That event is best known as part of the festivities now called the Green Corn Ceremony. Anthropologist Charles Hudson (1976) has compared this ceremony to the combined festivals of Thanksgiving, New Year's, Yom Kippur, Lent, and Mardi Gras.

The Green Corn Ceremony was the single most important event of the year in all southeastern groups. Essential items for the ceremonies were herbal teas. Several of the teas consumed were mixtures, and included emetics. The black drink included *assi* (*Ilex vomitoria*), and it became the most famous. Often recorded as an additive to black drink was *hici* or tobacco (*Nicotiana tabacum*). Among the other emetics used in the medicinal drinks were *pasa* or button snakeroot (*Eryngium yuccifolium*) and *oyihiliswa* (lizard's tail). One ritual and ceremonial medicinal tea called *ayikckanahki* (gathered medicine) contained up to 14 different plants.

Although the Muskogean people were accustomed to sharing their black drink and tobacco with visitors to the village square, the Green Corn Ceremony and its drinks were private affairs. Many secrets were kept about that event that they have not yet been

shared with the non-Muskogean world. In surviving practitioners, medicines and their preparations were then, as now, important events that were passed only from teacher to apprentice. Surely, that accounts for at least some of the uneven reports of *Saururus* among eastern United States people.

The Green Corn Ceremony was the Muskogean time of renewal when old animosities were forgiven, criminals tried, individuals purged of evil, and new children named. Ceremonial beverages used by south eastern people during this time played important roles, and *Saururus* is prominent in several of them. In each case the beverage aided in cleansing and refreshing before starting again.

We in the United States borrowed part of that custom, reworked it, and use it in an almost unrecognizable modified form. We no longer use lizard's tail, but the Coca-Cola Company once advertised our replacement as the "pause that refreshes."

### *Schaefferia*

(Jacquin named this for Jacob Christian Schaeffer, 1718–1790, a German mycologist and clergyman)

*Schaefferia frutescens*. a. Branch with pistillate flowers, b. Node, with leaf scar and bud with persistent lateral

stipules, c. Node, with axillary branch cluster, stipules fallen, d. Staminate flower, front-side view. e. Staminate flower, longitudinally dissected, f. Floral diagram of Staminate flower, g. Pistillate flower, from above, h. Pistillate flower, from below, i. Pistillate flower, longitudinally dissected, j. Floral diagram of pistillate flower, k. Branch with fruits. 1. Fruits. *Drawn by Priscilla Fawcett. From Correll and Correll 1982.*

***Schaefferia frutescens*** (shrubby)

*amansa guapo* (tamer of the wild, Cuba)

*boi de Persia cimarrón* (wild Persian tree, Cuba)

[Florida] boxwood (originally the Old World box-tree, *Buxus*, prized by wood-turners, wood-engravers, and used in the manufacture of mathematical and musical instruments, Florida,

Puerto Rico, Dutch Antilles)

*cabra [cimarrona]* ([wild] goat, Dominican Republic)

*cafecillo* (little coffee, Cuba, Puerto Rico)

*cambia voz* (voice changer, Cuba)

*[bois] capable* (competent tree, Haiti)

*fruta de paloma* (dove fruit, Venezuela)

*guairae* (the name resembles the Taino word *caguairin* for another Cuban tree)

*jasmín* (jasmine, Cuba)

*jibá* (also used for *Erithroxylum*, Taino, Puerto Rico)

*limoncillo* (little lemon, Colombia, Venezuela)

*marguerite* (a name usually applied to composites, such as *Melanthera*, Hispaniola)

*[petit] merisier* ([little] cherry, Guadeloupe, Martinique)

*mije* (an indigenous name, maybe Taino, Cuba)

*palo de araña* (spider tree, Dominican Republic)

*petit bois blanc [ti-bois blanc]* (little white tree, Haiti)

*[bois] petit garçon* (little waiter [tree], Haiti) yellow-wood (Florida)

After collecting plants in the Caribbean, Jacquin described this genus and species in 1760. There are now 16 *Schaefferia* species known, all of them in tropical America (Mabberley 1997).

Roig (1945) found *Schaefferia* being sold in markets in Santiago de Cuba and Havana under the names *amansa guapo* and *cambia voz*. No one would tell him what it was being used for, but he speculated it was an aphrodisiac. Liogier (1974) confirmed Roig's

suspicion. In addition, tea of the leaves is used in Haiti against flu and coughs (Liogier 1974).

The wood is used in construction (Liogier 1975). Little et al. (1974) described the wood as light brown to yellow, hard, moderately heavy, and fine textured. Under the names yellow-wood or boxwood it has served as a substitute for true boxwood (*Buxus*) in engraving.

### *Schizachyrium*

(From Greek *schizo*, to split, and *achyron*, chaff or husk, alluding to the toothed lemma)

*Schizachyrium scoparium*. Drawn by  
Mary Wright Gill and Agnes Chase.  
From Hitchcock and Chase 1950.

*Schizachyrium scoparium* (broom-like)

[broom] beardgrass; broom grass [bluestem]; broom sedge [sage]  
[little, pinehill] bluestem [little bluestem]

bunchgrass (this applies more to a growth form than a species)  
 prairie grass (indicators of prairie habitats)  
 wire grass (a name more often given to *Aristida*)

From at least 1753, one of the largest prairie grass genera was considered to be *Andropogon*. That genus received a number of species that were dominant plants in grasslands. Little bluestem remains one of the four most abundant and important grasses in the Great Plains, with *A. gerardii*, *Panicum virgatum*, and *Sorghastrum nutans* (Diggs et al. 1999). However, it was distinguished fairly late in history.

During the time André Michaux spent in South Carolina, he collected this grass. Subsequently, Michaux called it *A. scoparius* in his *Flora Boreali-Americana* (Flora of North America) published in 1803. Most authors retained it in *Andropogon*, but Christian G.D. Nees von Esenbeck (1776–1858), a German professor in Breslau, created a new genus for some of these grasses in 1829. He called the genus *Schizachyrium*. It was not until 1903, however, when John K. Small published the combination *S. scoparium* in his *Flora of the Southeastern United States*. Even then, most agrostologists continued using the older name (Hitchcock and Chase 1950).

As now understood, *Schizachyrium* is a genus of mostly tropical grasses with 60 species, particularly common in savannas. *Schizachyrium scoparium* grows from Quebec to Alberta and from Maine to Montana, south through Idaho, Arizona, and Florida; other varieties grow from Texas and Arizona to Coahuila, south to Nuevo León, and San Luis Potosí (Hitchcock and Chase 1950, Correll and Johnston 1970).

Comparatively few uses are recorded for grasses among indigenous American tribes. Most of those recorded have been used as thatch, and others are known as foods (e.g., *Zea*, *Zizania*) and medicines.

*Schizachyrium scoparium* was first reported among the Ozark Bluff-Dwellers of Arkansas by Gilmore (1931). Subsequently, Marie Standifer et al. (2003) found this grass among archaeological items in Arnold Research Cave, Missouri. People who used the Missouri area had padded their sandals with little bluestem. Presumably, they were to help them keep warm, just as they were by the historic people. The Lakota used the plants much like the prehistoric people in Missouri (Moerman 1998). These plains people rubbed the grasses into softness and used them as insulation in their moccasins during the winter. They also used *Andropogon gerardii* (big bluestem) and *Eryngium yuccifolium* for the same purpose (Standifer et al. 2003).

Other people had several uses for little bluestem. The Comanche made bundles of the stems for switches in the sweat lodge (Moerman 1998). The Comanche also burned the stems and applied the ashes to help cure syphilitic sores (Vogel 1970).

### *Scirpus*

(Ancient Latin for the bulrush; the name used by Pliny, A.D. 23–79; a cognate word in Hebrew is *haber*, joined, united, as in weaving mats from the stems)

bull-rush (from Middle English *bulrysche* or *bolroysche*, from ca. 1440);  
 club-rush

*giunco* (from Latin *juncus*, Italian); *jonc* (French); *junco* (Spanish)

***Scirpus americanus*.** From Britton and Brown 1896.

*luachair* (also means brightness, Gaelic)

*meithean* (Gaelic)

*Simse* (German)

*souchet* (refers to any sedge but mostly applied to *Cyperus* spp.; derived from *souche*, a stem or stock, itself from Gaulois *tsukka*, corresponding to German *Stock* (*st-* becomes *ts-* in Celtic; in use in French by 1375; cognates in Italian are *soc*, *socca*, and in Spanish *zoque*)

***Scirpus americanus*** (American)

American bulrush

***Scirpus tabernaemontani*** (named for German herbalist Jakob Theodor von Bergzaben, 1520–1590, who Latinized his name to Tabernaemontanus, “tavern in the mountain”) (= *S. validus*)

*ana'gûnûsk* (mat weed, woven into mats, Potawatomi); *ana'kun* (Ojibwa)

[softstem] bulrush [bullrush] (USA)

chairmaker's rush; rush (perhaps from Germanic words, from Old English *risc* or *rix* and *rise* and *rix*, Middle Dutch *risch*, and Middle Low German *risch(e)*, *rysse*, *risk*, *ryse*, dating to about A.D. 725)

*énea* (copper colored, Spanish)

*I'herbe a souris* (mouse herb, Houma, Louisiana)

*psa* (Dakota); *sa-hi* (*hi*, plant, Omaha-Ponca)

rat grass (Louisiana)

*sistat* (Pawnee)

sword grass (descriptive of the culms)

*tule* (Spanish and English, from *tollin* or *tullin*, Náhuatl)

Siméon ([1885] 1981) wrote of the *tollin*, “*El tollin servía para hacer estreras o petlatl, lo que constituía, sobre todo en tierra de los toltecas, una industria importante*” (The rush served to make matting or *petlatl*, which constituted, through the whole land of the Toltecs, an important industry). Different species of these plants have been used for mats throughout the world (Hocking 1997). Moerman (1998) listed 12 species that have been used by indigenous people all over North America.

In North America perhaps the first report of prehistoric people using *Scirpus* was by Gilmore (1931). He identified *Scirpus tabernaemontani* that had been used to weave bags and mats at the Ozark Bluff-Dweller site in Arkansas. Later historic people continued weaving them.

*Scirpus americanus* was used by at least the northwestern groups including the Hanaksiala, Keres, Kwakiutl, Makah, Nitinaht, Pomo, and Salish (Moerman 1998). *Scirpus tabernaemontani* was used by the Cherokee, Cree, Dakota, Kawaiisu, Hopi, Iroquois, Lakota, Meskwaki, Menomini, Ojibwa, Omaha, Pawnee, Ponca, Potawatomi, and Ute (Gilmore 1919, Densmore 1928, Smith 1933, Yanovsky 1936, Moerman 1998). These people used both species for medicines, foods, and fibers. Yanovsky (1936) found records of *S. tabernaemontani* being used for food in California, Michigan, Minnesota, Missouri, Nebraska, New York, North Dakota, South Dakota, Montana, and Wisconsin. Roots were dried and pounded into flour that, mixed with pollen, was made into bread.

Seminole relatives the Koasati and Houma both used *Scirpus* (Taylor 1940, Speck 1941). Among the Houma *Scirpus* was used as a wash for weak legs, and given as a decoction to quiet nervous, fretful, and crying children (Speck 1941). They also made the dried plants into brooms.

### ***Scoparia*: Sweet-Broom**

(Latin *scopa*, broom of twigs)

Sweet-broom, a widespread herb in the tropics, is commonly found as a weed near houses. It would go too far to say it was cultivated, but it is at least tolerated. The most common references to it are to use as a broom—stems are bundled and used to clean the area around and within homes. That this practice is old is reflected in the scientific as well as most of the common names.

This is *Scoparia dulcis*, the sweet broom. That name was applied by Linnaeus in 1753, but it was a shift from his earlier use. In his study of the private garden of George Clifford, published as *Hortus Cliffortianus* in 1738, Linnaeus called it *Capraria foliis ternis, corollis quadripartitis* (goatweed with leaves in [groups of] three and a four-parted corolla). He knew it from Jamaica and Curaçao, where its modern names

*Scoparia dulcis*. a. Fertile branch, b. Leaf. c. Section of leaf showing glands, d. Node. e. Flower, from below, f. Flower, front-side view. g. Flower, longitudinally dissected, h. Floral diagram, i. Fruit. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

are sweet broom (Florida, Georgia, Louisiana, Texas, Jamaica), *bezemkruit* (broom weed, Dutch Antilles), and [switi] *sisibi-wiwiri* [siebie wiwirie] (switi, sweet, sisibi, sweep, wiwiri, leaf, Sranan, Suriname). In 1753, Linnaeus switched names and called another plant *Capraria*, and this one he based on a translation of its common name, sweet-broom.

Not everyone agrees that it should be called “sweet,” but many agree on its use as a broom. In French, it is *balai doux* [balié doux, balais doux, balé dou, balye du] (sweet broom, Haiti, Dominica, Trinidad), *balai savane* (savanna broom, Guadeloupe, Martinique), *balié sauvaj* (wild broom, Haiti), or *herbe à balai* (broom herb, French Antilles). In Spanish, it becomes *escoba dulce* (sweet broom, Venezuela, Panama), *escobeta* (little broom, Central America), *escobilla* (little broom, Cuba, Honduras, Venezuela), *escobilla menudita* (tiny little broom Colombia), *escobo dulce* (sweet broom, Colombia), or *pichanga dulce* (sweet broom, Colombia). Even *miel de tierra* (earth honey, Argentina) is a reference to the sweetness, although not to the broom. In

Nicaragua, it is *brum sirpi* (sweet broom, Miskito) and *brum tahplira* (sweet? broom, Miskito).

Those who do not think it sweet call it *escoba [escobita] amarga* (bitter [little] broom, Puerto Rico) or *escobilla amarga* (bitter little broom, Puerto Rico, Costa Rica, Panama, Venezuela). Sometimes it is *escoba de Castilla* (Spanish broom, Costa Rica), although it does not grow in Spain. People speaking Portuguese say *vassourinha [bassourinha]* (little broom, Amazonas, Brazil), *vassourinha de botão* (button broom, Brazil), or *vassourinha de varrer* (broom-branches, Minas Gerais, Brazil). Sometimes it is broomwort [sweet broomwort] (Texas) in English. All those names probably originally came from South America where it is *ñucñu-pichana* (sweet broom, Quechua, Peru), *piqui pichana* (sweet? broom, Peru), and *tupixaba [tupiçaba, tapixava, tapixapa, tapeiçaba, tupeiçaba, tupeicaba]* (broom, from Tupí *tui'xaba*, Minas Gerais, Brazil) (Pereira 1949).

Some of the local names are either untranslated or obscure. These include *bati matsoti* (Peru), *buñiga [buñiga]* (Hispaniola), *haraspata* (Miskito, Nicaragua), *kukibiu edan* (Arawak, Suriname), *mariquita* (also name for a beetle, Costa Rica), *paraguay* (presumably a word in Guaraní, Colombia), *shikiskiki tokon* (Carib, Suriname), *sirsaika* (Miskito, Nicaragua), and *sur'préjsi* (Paya, Nicaragua).

Two reported names are suspect (Pérez-Arbelaez 1978); both *azafran de la tierra* (wild saffron, Colombia) and *color* (roots used for coloring, Colombia) refer to use as a substitute for saffron (*Crocus sativus*). Those people who call the plants *chile de pajarito* (bird chile, Mexico) or *hierba de pajarito* (little bird's herb, Mexico) see something that is not obvious to the rest of us. The seeds are so tiny that they would barely be noticeable to all but the smallest seed-eating birds.

On the other hand, many of the comparisons are more easily understood, whether we agree or not. Because of its fragrance, one might compare it to anise (*Pimpinilla anisum*), as do people who call it aniseed [pine-ridge anise-seed] (Belize), anise-seed bush, or *anisillo* (Nicaragua). Others think it is more like coriander (*Coriandrum sativum* or *Eryngium foetidum*) and say *culantrillo* (little coriander, El Salvador, Belize), *culantro* (coriander, El Salvador), *culantro de pollo* (chicken's coriander, Central America), *culantro moniés* (wild coriander, Central America), or *culantropim* (Belize). The same views apply to comparing it with *mastuèrzo* (nasturtium, *Tropaeolum majus*, Cuba, Hispaniola, Puerto Rico, Costa Rica).

The plants are small and herbaceous, but otherwise not much like *arrocillo* (little rice, Central America), rice weed (Nicaragua), or wild rice (Nicaragua). However, others make a similar comparison with *orozuz* (from Arawak, *oro çuç*, root of a legume, Puerto Rico) and *orozuz de pasto* (grass *orozuz*, Puerto Rico). Why *Scoparia* is compared to a *bruscón* (resembling *brusca*, medicinal herbaceous *Cassia*, Venezuela), *cancharagua* (*canchalagua*, a medicinal Gentianaceae, Hispaniola), or *verbena silvestre* (wild verbena) is obscure except that all are used as medicines.

Medicinal uses are common, and many of the names also carry that implication. In Mexico, it is *yerba del golpe [hierba del golfe]* (herb for bruises), and there is a widespread view that any bruise or other injury is cured by the plant. One of the common preparations is in teas. That product leads to the names licorice weed (USA, Puerto Rico), *té* (tea, Chiriguana, Colombia), *thé savane* (savanna tea, Guadeloupe, Martinique), and *typychá kuratu [typycha caratu]* (probably Guaraní, in related Tupí, *tipi* is *Petivaria*

*alliacea*; *chá*, tea, Paraguay). In “tea” it is applied as an abortifacient or contraceptive (with or without *Chenopodium ambrosioides*), antiemetic (with mother’s milk for infants), antifilarial, aphrodisiac, in baths, to purify blood, for bronchitis, colic, coughs, diarrhea, earaches, as an emetic, to treat erysipelas (infected wounds), eye ailments, fevers, wounds, hemorrhoids, kidney disease, pain, in poultices for migraine, as a purgative, against snakebite in a plaster with salt, and to treat swelling, urine retention, and venereal diseases (Liogier 1974, Morton 1981, von Reis and Lipp 1982, Duke and Vásquez 1994, Gupta 1995a, Mors et al. 2001). According to the name teeth bush (British Antilles), the plant is used as a tooth cleaner. In Ecuador, it is named *tiatina* (Los Rios Province, Ecuador), presumably for Aunt Tina who may have been a *curandera*.

The plants contain alkaloids, salicylic acid, sisterol, hexacosanol, D-mannitol, tritriacontane, dulciol, scopanol, dulcione, 6-methoxybenzoxazolone, betulinic acid, ifflaionic acid, scoparic acid A, scopadulcic acid A, scopadulcic acid B, and other compounds (Willaman and Schubert 1961, Chen and Chen 1976, Mahato et al. 1981, Morton 1981, Kawasaki et al. 1987, Hayashi et al. 1988c, 1990a, 1992). The whole plant has been shown to be a central nervous system depressant (Jiu 1966), so that may be why it has been used as a marijuana substitute (Duke and Vásquez 1994). Since the fresh or dried plants have been used to kill fleas and lice, and put in baths to kill vermin (Altschul 1973), smoking it is problematical and dangerous.

At one point it was thought that a compound called amellin from *Scoparia* was antidiabetic (Nath and Banerjee 1943, Whittaker 1948). However, a single subsequent study did not support that view and it was abandoned (Budde and Shriner 1950). Duke et al. (2002) suggested that the plants should be reexamined for that compound.

Extracts from *Scoparia* have even been used in Nicaragua to treat malaria. A study by Riel et al. (2002) showed that several compounds from the herbs have direct inhibitory activity against porcine gastric H(+), K(+)-ATPase. They further found that there was considerable activity against *Plasmodium falciparum* in the laboratory, and they suggested a mechanism for this inhibition of malaria through proton pump action (Asano et al. 1990, Hayashi et al. 1991).

Studies by Hayashi et al. (1988a, 1990b) and Riel et al. (2002) have shown that scopadulcic acid B from the herbs is antiviral. The compounds are effective against *Herpes simplex* virus type 1. In addition, compounds have been isolated and tested that were analgesic, diuretic, and anti-inflammatory (Freire et al. 1991, Ahmed et al. 2001). Scoparinol, a diterpene, showed significant analgesic and anti-inflammatory activity in animals (Ahmed et al. 2001). Furthermore, a sedative action of scoparinol was demonstrated with a significant effect on both onset and duration of sleep (Ahmed et al. 2001). There was also diuretic action by scoparinol. Freire et al. (1991) suggested that the analgesic activity might be explained by an antiinflammatory activity of the triterpene glutinol.

Pereira-Martins et al. (1998) found a mutagenic effect of the flavone cirsitakaoside when it was tested in human blood cultures, but not when Swiss mice were treated orally. Cytotoxicity was also previously reported by Hayashi et al. (1988b). Riel et al. (2002) found antitumor activity in various human cell lines. Nishino et al. (1993) noted that the inhibition was due to scopadulcic acid B. Nishino et al. (1993) further indicated, “The potency...proved to be stronger than that of other natural antitumor-promoting terpenoids, such as glycyrrhetic acid.”

Lans et al. (2000) found people in Trinidad and Tobago treating their dogs with herbs, including *Scoparia*. Leaves are used to control ectoparasites and to groom animals. Apparently, if an herb is good enough for people, it is all right to use on their dogs. Or, is it the other way around?

Many years ago, these herbs were taken to the Old World. Their common names *teh makao* (Macao tea) and *cha padang* (tea of open places) suggest that they were carried from China into the Malasian Peninsula. However, the Malay name for them distills sweetbroom's reputation in the New and Old World—*bunga baik salam* (good flower of peace).

### *Scrophularia*

(Named this by Linnaeus because some species have fleshy knobs on the rhizomes; these were thought to cure “scrofula” and remove “fig-warts”)

*Braunwurz* (brown herb, in use by 1542, German); *brunrot* (brown root, Norwegian)

*escrofularia* (from Latin *scrophularia*, Spanish, Portuguese); *scrofolaria* (Italian); *scrofulaire* (French)

figwort (a name applied to a variety of plants; in use by the time Turner wrote his *Names of Herbes* in 1548; so called because it was thought to cure “fig-warts,” a disease in humans resulting in a growth resembling figs or *Ficus*; applied both to piles and warts; the name of the disease was in use by the 1400s)

*lus nan cnapan* (knobbed plant, Gaelic)  
water betony

### *Scrophularia marilandica* (of Maryland)

brown-wort [brownwort] (in use as “broune wurte” by 1578)

bull-wort [bullwort] (“wort” is archaic English for “herb”)

carpenter's square (because of the square stems); square stalk  
[Maryland] figwort

heal-all (a name applied to several kinds of plants, including several mints)

Holme's weed

kernelwort

knotted root

*Kropfwurz* (swelling plant, German)

murrian grass

[great] pilewort (because of its used in treating piles or hemmorhoids; “pilewort” was applied to *Ranunculus ficaria* by the 1570s; later to *Scrophularia*)

scrofula plant; *Scrophelnplanze* (scrofula plant, German)

stinking Christopher (an English dialectic name for *Scrophularia*; Millspaugh 1892 wrote, “All parts of the plant have a heavy, rank odor when bruised”)

John Parkinson wrote in 1640 that a European species of *Scrophularia* was “effectual for the Kings Evil, or any other knots, kernels, bunches or wennes growing in the flesh wheresoever: it is of singular good use to be applied for the hemorrhoids or piles, when they grow painfull and fall down, and for other such knobbes or kernells as sometimes grow in and about the Fundament” (Coffey 1993). The name “Kings Evil” was a translation from Latin *regius morbus*, and from the 14th century A.D. it was thought in England and France to be curable by a king’s touch. The same disease, called scrofula (from Latin *scrofularia*, a swelling or tumor), was tuberculosis of the lymph nodes, particularly in the neck.

Linnaeus described *S. marilandica* from plants John Clayton collected in Virginia, and those growing at the *Hortus Upsaliensis* at the university in Sweden. We now know that *S. marilandica* grows from south-western Maine and southwestern Quebec to Minnesota, south to South Carolina, northern Georgia, Alabama, Louisiana, and Oklahoma (Fernald 1950). The species barely reaches Florida, being known only from Gadsden, Jackson, and Taylor Counties. Although the genus was popular with Europeans as a medicine, the indigenous people of the Americas apparently used it less. Only two tribes are recorded as employing the plants. The Iroquois gave an infusion to women with irregular menses. The Meskwaki used the plants in an undisclosed medicine (Moerman 1998). Elsewhere in North America, we know of only three other species used.

Porcher (1863) wrote tersely of *S. marilandica*, “It is vulnerary and soothing, when applied as a poultice to ulcers, burns, etc.” On the other hand, Millspaugh (1892) thought that *S. nodosa* of Europe and the American *S. marilandica* were equal in effectiveness. He noted, “This herb is said to serve as a soothing poultice to inflamed tumors, suppurating mammae, ulcers, burns, hemorrhoids, etc.; it is also used alone and as a component of salves, for itch, various eruptions, and ‘scabs’ in swine, as well as a tonic and deobstructant in hepatic and glandular disorders.”

More recently, Foster and Duke (1990) wrote that *S. marilandica* was applied in a poultice as a domestic cancer remedy, and used to allay restlessness, anxiety, and sleeplessness in pregnant women (Foster and Duke 1990). Hocking (1997) added that it was emmenagogue, alterative, and vulnerary (Hocking 1997).

Not much has been done on the chemistry of *Scrophularia*. Millspaugh (1892) reported scrophularin and scrophularosmin, a stearoptene in the plants. Lewis and Elvin-Lewis (1977) found that the genus contains cardiac glycosides, especially in *S. aquatica*, but poisoning is rare because of the unpleasant taste and odor. Bown (1995) found that *S. nodosa* contains aucubin, a mild laxative that increases excretion of uric acid and harpagide; it is recommended for skin problems. Bown (1995) and Duke et al. (2002) cautioned against use of the herbs by those with heart problems.

### *Scutellaria*

(From Latin *scutella*, a small dish, in reference to the protuberance on the calyx)

***Scutellaria havanensis*.** a. Flowering stem. b. Flower, front view. c. Flower, side view. d. Flower, longitudinally dissected, e. Ovary, f. Fruit, g. Floral diagram. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

***Scutellaria havanensis*** (from Havana, Cuba)

*escudo de la Habana* (Havana shield, Cuba)

skullcap (in use by 1682 for any close-fitting cap; the helmetlike protuberance on the calyx prompted comparison by 1760, Florida, Bahamas)

*toque de la Havane* (Havana cap, Martinique)

Linnaeus ([1753] 1957) recognized 12 species in *Scutellaria* when he described the genus. He did not coin the generic name, but borrowed it from several authors before him. The genus has grown to about 350 species, and Mabberley (1997) considered it cosmopolitan. There are 13 species in Europe, and Kartesz (1993) admitted 44 for North America.

This herb is used in Cuba to treat spleen infections, edema, and *enasarca* (mange). Seeds are used against psoriasis, and sarcoptic mange (Roig 1945). Oddly, Morton (1981) did not include this species of *Scutellaria*; Ayensu (1981) did not even include the genus.

The Cherokees use three species of *Scutellaria* (Hamel and Chiltoskey 1975). Hairy skullcap (*S. elliptica*), hoary skullcap (*S. incana*), and blue skullcap (*S. lateriflora*) are considered abortifacient. They are used to relieve painful breasts and are mixed with

other plants to expel the afterbirth. A mixture of other plants with roots of either species is also a kidney medicine. The Iroquois also use *S. lateriflora*, but for cleaning the throat (Moerman 1998). The Delaware use *S. incana*, and the Meskwaki *S. parvula*, so there was considerable application of the genus in the eastern United States.

In Jamaica, *S. viminea* has been boiled with ginger to treat colic (Morton 1981). Costa Rica's Bribri tribe use a decoction of *S. costaricana* as a febrifuge (Morton 1981). Presumably, the lack of data on Florida people using *Scutellaria* is an absence of information and not use.

## Senna

(Philip Miller adapted the Arabic *sana* or *sanna* for the plants)

*Senna ligustrina* (resembling privet) (= *Cassia bahamensis*)

*brusca* (prompt, Hispaniola; surely a comment on use as a laxative)

*canéfica båtard* (false cassia; *cassia* is an old Greek name, *kasia* or *kassia*, of Semitic origin, akin to Hebrew *qase'ah*, *qesi'ah*, or *quetsiah*, used for an aromatic and fragrant shrub, Guadeloupe, Martinique)

*cassee savane* (savanna cassia, Guadeloupe, Martinique); *cassee sene* (cassia senna, French Antilles)

Christmas flower (Bahamas)

dandelion (both have yellow flowers, Bahamas)

Gilead bush ("Balm of Gilead" [Jordan], from *Commifera*, is also medicinal, Bahamas)

piss-a-bed (Jamaica)

privet senna (Puerto Rico); privet wild sensitive plant (Florida)

*sen [de la tierra, del país]* (country senna, Cuba); *sénné zombi* (zombie senna, Guadeloupe, Martinique)

stink bush (Bahamas); stinking pea (Bahamas); *yerba hedionda* (stinking herb, Cuba)

Like many others in the genus, *Senna ligustrina* is a sometimes drastic purgative (Standley 1920–1926, Roig 1945). Surprisingly, this species is not among the poisonous species listed for Florida by Perkins and Payne (1978). Most, if not all, of the species owe their action to anthraquinones, although lectins and other compounds are known (Lewis and Elvin-Lewis 1977, Perkins and Payne 1978, Lampe and McCann 1985). The exact action on the body seems to be dose dependent.

In the Bahamas, leafy branches are boiled and the decoction taken for fever or stomach trouble. Branches are boiled with *Ambrosia hispida* and *Turnera ulmifolia* to treat menstrual cramps. Leaf juice is applied to hemorrhoids and used to draw out boils. Roots and leaves mixed with *Randia aculeata* help discharge afterbirth (Ayensu 1981). Cubans use the leaves as a purgative and to stimulate the bladder and uterus (Roig 1945). Haitians make remedies of the pods to treat chronic constipation (Morton 1981).

Several species occur in Florida, although most of them are introduced (Wunderlin 1998). The temperate species are covered in more detail by Moerman (1998).

***Serenoa*: Saw Palmetto**

(Named by Sir Joseph Dalton Hooker for the Harvard botanist Sereno Watson, 1826–1892)

When I first saw the scientific name of the saw palmetto, *Serenoa repens*, I thought it unusually appropriate. The genus appeared to be based on “serene,” and the species *repens* means reclining. How poetic it seemed for plants with their stems lying peacefully on the ground. Then, I learned that the genus was created to honor Sereno Watson, an introverted assistant to Asa Gray at Harvard University. So much for poetry.

The first European to mention saw palmetto was Spaniard Hernando Descalante Fontaneda ([1575] 1944). He called the shrubs both *palma* and *palmito*, and recorded how important they were to the people living in Florida. Quaker merchant Jonathan Dickinson called them a “shrubby palmetto” in the 1690s (Andrews and Andrews 1945). Historian Barcia (1565) and surveyor Romans ([1775] 1961) called the palm *Chamaerops*. They mistook *Serenoa* for a relative of the dwarf palm of the Mediterranean coast, *Chamaerops humilis*. It was William Bartram who coined the name “saw palmetto” that we use today (Bartram [1791] 1958).

Bartram also applied the Latin name *Corypha repens*, which became the basis for the modern name, *S. repens*. It was on St. Simon’s Island, Glynn County, Georgia that Bartram first noted the plants, and he wrote of seeing “many curious vegetable productions, particularly *Corypha palma* (or great Cabbage Palm) [*Sabal palmetto*], *Corypha pumila* [*Sabal minor*], *Corypha repens*, frondibus expansis, flabelliformis, plicatis, stipit. spinosis (Dwarf Saw Palmetto).” In his *Travels*, Bartram ([1791] 1958) wrote that the berries were “delicious and nourishing food.” Dickinson did not agree, at least on his first attempt, and wrote that the fruits were comparable to “nothing else, but rotten cheese steeped in tobacco” (Andrews and Andrews 1945). When Bartram was interviewed later about plants used by the Creeks, he admitted that the fruit “is a little bitterish and stinging on the palate, at first using it, but soon becomes familiar and desirable” (Bartram 1853).

These fruits were important to people throughout their range from North Carolina to Florida, west to southwestern Louisiana and southeastern Texas. Our first records of use in Florida come from a preColumbian Glades site on Lake Okeechobee (Hogan 1978). Hahn (1986) also found records of use among the Timucua and Apalachee. The Calusas with whom Fontaneda lived and the Jobé who met Dickinson ate them fresh. The Choctaw near the Mississippi River also dried the fruits for winter use (Romans [1775] 1961), as did their Siouan-speaking neighbors who called them *amashû’pka* (Ofo), *maxontkxo’hi a’naki* (ancient palmetto fruit, Biloxi), or *ta’carahc* (Tunica). The Atakapa said *ma’kpel*.

*Serenoa* is *tala* (palm) to the Alabama and Choctaw. In related Muskogee it was *seyapho* [*seopho*, *shiopo*] (Simmons [1822] 1973, Bennett 1997). In a transfer resembling the one with the opossum and pig (see discussion in *Sagittaria*), the old name *seyapho* is now also applied to the date palm (*Phoenix dactylifera*) (Martin and Mauldin 2000).

*Serenoa* fruits are *siyá:pho intá:la* (*seyapho*, the fruits, *em+talv*, its palm, Creek) and *siyaphintá:lî* [*sheopein taale*, *sheop’n taale*, *sheopo entaale*] (*sheope*, the fruits, *im*, its, *taale*, palm, Mikasuki). Older Seminoles still consume the fruits in a drink called *shiope*

*sofkee* (palmetto gruel). Bennett and Hicklin (1998) consider this palm the most versatile plant in Florida, providing food, fiber, oil, medicine, wax, and roof thatch.

The Choctaws, Creeks, and Miccosukees used the leaves for making baskets (Bushnell 1909, Sturtevant 1955, Bennett and Hicklin 1998). Those baskets were used for a variety of purposes, including medicinal preparations. Leaves were also made into brushes, ropes, rattles, dance fans, fire fans, as punk for flint and steel fires, fish “drags,” dolls, and tourist goods (Sturtevant 1955, Moerman 1998). Like most palms, the “heart” of saw palmetto is edible (Morton 1968b). There is, however, no documentation of native people in North America using palm hearts before Europeans arrived.

Fruits contain fatty oil, usually scarce in indigenous diets, with triglycerides including capric, caprylic, carioic, lauric, palmitic, and oleic acid (Bennett and Hicklin 1998). Berries also have phytosterols, their

***Serenoa repens*.** Inflorescence, branchlet with fruits, and leaf (above). Habit (below). *Drawn by P.N. Honychurch.*

esters and glucosides, tannins, resins, and up to 28% sugars (Hocking 1997). American tribes used it as a diuretic, sedative, and anti-inflammatory, for asthma, colds, coughs, chronic bronchitis, diarrhea, prostate problems, and migraine (Krochmal and Krochmal 1973, Foster and Duke 1990, Tyler 1993, Hocking 1997, Bennett and Hicklin 1998).

The species was listed in the U.S. National Formulary until 1952 (Bennett and Hicklin 1998). Then, in the 1960s, Europeans discovered that the fruits of *Serenoa* showed estrogenic activity, which was attributed to the high content of beta-sitosterol (e.g., Kloss 1966, Elghamry and Haensel 1969).

Later, it was rediscovered that benign prostatic hyperplasia (BPH) could be treated with phytosterols, particularly beta-sitosterol (e.g., Wagner and Flachsbarth 1981, Tarayre et al. 1983, Hiermann 1989). This discovery started a debate that remains unresolved.

In the past two or so decades literally dozens of papers have been written about “tests” of the efficacy of saw palmetto extracts. A small sample includes papers by Flamm et al. (1979), Carbin et al. (1990), Breu et al. (1992), Romics et al. (1993), Vahlensieck et al. (1993, 1996), Schneider et al. (1995), Gutierrez et al. (1996a,b), Kondas et al. (1996, 1997), Weisser et al. (1996, 1997), Bartsch et al. (1998), Ondrizek et al. (1999), Schilcher (1999), Wagner (1999), Medvedev et al. 2000), Sokeland (2000), Koch (2001), Lowe (2001), Dreikorn (2002), Ernst (2002), and Lowe and Fagelman (2002).

A recurrent theme among those against the use of saw palmetto is that there have been “no double-blind studies” (e.g., Lowe 2001, Ernst 2002, Lowe and Fagelman 2002). However, there are at least four studies using that approach that were not mentioned by these critics (Carbin et al. 1990, Weisser et al. 1997, Sokeland 2000, Prager et al. 2002). Another complaint is that past studies have not been long enough. Some argue that tests should be at least 6 months long to “show” if the phytomedicine is effective (Lowe 2001). That argument should have been silenced years ago, because Romics et al. (1993), Kondas et al. (1996, 1997), and Sokeland and Albrecht (1997) did studies longer than 6 months in duration. Moreover, Sokeland and Albrecht (1997) not only did a 1-year study, but it was also double blind.

Germans have pioneered both chemical and clinical research on saw palmetto and BPH. The impression gained by reading the literature on this topic is that some physicians are not willing to believe research done outside their own country. Surely, there is abundant healthy skepticism in the slowness of physicians to accept the possibility of the effectiveness of *Serenoa* extracts, but there is also an aura of sovereignty in their criticisms. Could it also be a remnant belief that only compounds synthesized by humans can be effective?

A major complication to accepting the idea that a plant extract can be effective is that no one understands just what happens in BPH. Everyone knows that there is tissue swelling, and that anti-inflammatory compounds help, but it is not that simple. There is no correlation between the amount of swelling and the magnitude of urinary retention. Several scenarios have been suggested for the mechanism and for treatment, but no one is yet sure which is correct. Worse, they may all be involved.

The standard approach by U.S. urologists is invasive surgery. Some doctors will attempt one of the three routes of medication, using the “party standards” alfuzosin and terazosin, while others will attempt the alternative synthetic drug finasteride (Wilde and Goa 1999). These drugs have different mechanisms of action, with the former an alpha-

adrenoceptor blocker, and the latter inhibiting 5-alpha-(testosterone)-reductase (Schilcher 1998). Because phytomedicines are cheaper and as effective, and have none of the adverse side effects, many German physicians prescribe them (Schilcher 1998).

The debate over whether or not saw palmetto phytosterols are effective is not likely to end soon. Still, I have to point out a datum that no one has yet mentioned. Over two centuries ago Bartram ([1791] 1958) noted that bears (*Ursus americanus*) also ate saw palmetto berries. Has anyone ever heard of a bear having BPH?

What is not apparent to the physicians, or to their patients, is that the environment in the range of *Serenoa repens* is being ravaged in the public demand for this phytomedicine (Bennett and Hicklin 1998). Each year in Florida both state and national park officers are stopping more trespassers who are poaching saw palmetto fruits. No one knows the impact of continued harvesting of the fruits on the population dynamics of this formerly common plant. In some areas, the palmettos are now uncommon. At first, cattle farmers were delighted that there might be a reduction of these “weeds” in their pastures. Then, in years when prices are high, some have even excluded harvesters and gathered fruits from their own property.

In the United States, a country with an aging population, individuals rarely know or care about debates over effectiveness, much less habitat devastation. About 25% of men between 40 and 50 are afflicted with BPH, and nearly 80% older than 70 have it (Schilcher 1998). Most men suffering from the problem simply want relief. If saw palmetto works, and is cheaper than prescription drugs, they will use it. If saw palmetto works for bears, why not people? Some of my friends say I am an “old bear,” and it works for me.

### *Sesuvium*

(Perhaps derived from Latin *sesuvii*, a Gallic tribe west of the Seine)

***Sesuvium portulacastrum*** (with flowers resembling *Portulaca*)

*azucena de mar* (sea *azucena*; usually *azucena* is the tuberose, *Polianthes tuberosa*, Agavaceae, Puerto Rico)

*banana di rif* (reed banana, Aruba, Bonaire, Curaçao); *platanillo* (little banana, Dominican Republic)

bay flowers (Virgin Islands)

***Sesuvium portulacastrum*.** Drawn by  
P.N.Honychurch.

*beldroega de praia* (beach purslane, Brazil); *pourpier bord de mer [la mer]* (seaside purslane, Haiti, Guadeloupe, Martinique); sea purslane [sea pusley, seaside purslane] (Florida to Panama); *verdolaga de la playa* (beach purslane, Cuba, Puerto Rico, Guatemala); *verdolaga rosado* (pink purslane, Puerto Rico, Costa Rica); *verdolaguilla* (little purslane, Dominican Republic)

*camburito* (little banana, Venezuela)

*ceniceinta [cenicilla]* (little ash-colored one)

*conejera* (mother of rabbits); *herba [yerba] de conejo* (rabbit herb, Venezuela)

*coupe pieds* (literally “foot-cutter,” unexplained, French Antilles); *coupier* (“foot-cutter,” French Antilles)

seaside samphire (Barbados)

*tsaycan* (viper’s fang, because of the leaf shape, Maya, Guatemala)

*vidrillo* (little glass); *vidrio* (glass, Venezuela); *yerba [hierba] de vidrio* (glass herb, Puerto Rico, Venezuela)

Linnaeus at first called these plants *Portulaca portulacastrum* in 1753. Then, realizing his error, he created the name *Sesuvium* in 1759. There are now 12 species in warm parts of the world (Mabberley 1997).

Although these beach plants were apparently used more commonly in the past, few now seem to apply them. In Cuba, the stems and leaves are considered emollient, resolute, refreshing, and were used against scurvy. On both Cuba and Hispaniola, the seeds are said to be a vermifuge (Roig 1945, Liogier 1974), although Morton (1968b) said they were a famine food. Plant stems and leaves are edible raw or pickled, are antiscorbutic, and salty, although in Haiti, the juice also is given as a vermifuge (Morton 1981). In Hispaniola, the plant is edible, and considered emollient and fortifying (Liogier 1974). *Sesuvium* is cultivated as a vegetable in Asia (Morton 1968, Hocking 1997). The common names suggest that sea purslane has been used as rabbit food.

In Argentina, a decoction is given for bladder, liver, and kidney problems. Hot poultices are used for chest congestion, and cold poultices plus a plant decoction are put on burns (Morton 1981). *Sesuvium* is one of richest sources of ecdysterone; it also contains alpha-ecdysone, a rare insect-molting hormone, and sesuvin (flavonol glycoside) (Morton 1981). In Asia, sea purslane is considered hemostatic, and used for wounds, especially for the stings of toxic fishes (Hocking 1997).

### ***Sideroxylon*: Mastic and Bustic**

(From Greek *sidero*, iron, and *xylon*, wood, a reference to the hard wood)

***Sideroxylon foetidissimum*. Drawn by  
P.N.Honychurch.**

Spaniards arriving in the New World brought with them the word *almástiga* (from Arabic *al+mastika*). That became “mastic” in English, and both referred to the Old World tree *Pistacia lentiscus*, a relative of cashews (*Anacardium occidentale*), mangos (*Mangifera indica*), and poison ivy (*Toxicodendron radicans*). Both words are cognate with Latin *mastichus* and Greek *mastikon*, to chew, from a use of the sap as chewing gum. Mastic sap also has other applications; it is used as glue, as a protective coating, for coloring, and in an alcoholic liqueur flavored with mastic sap and anise seed (Austin 1981).

Europeans found the people in the Caribbean using a similar sap. Today these American trees are *Sideroxylon foetidissimum*, a name applied by Nicolaus Jacquin in 1760. The species is *foetidissimum* (most offensive smelling) because of the foul odor of the flowers. Walk downwind of a tree in flower and you will think that something is dead and decaying.

However, by the 1760s the American plants had usurped the Old World names, and were “mastic” (Florida to Panama) and *almástiga* (Spanish). Bernard Romans ([1775] 1961), who surveyed coastal Florida in the 1760s, listed the trees near today’s Vero Beach. Romans’s use was a Middle English spelling “mastick,” but the name was firmly entrenched.

Today people call these trees Barbados mastic (Barbados), bully-mastic [mastic-bully] (Bahamas, Jamaica, Puerto Rico, Virgin Islands), false mastic (Florida, Puerto Rico), mastic jungle-plum (Florida), mastic-wood (Jamaica, Virgin Islands), mastwood (Virgin Islands, Antigua, St. Vincent), and wild-mastic (Florida).

In the Caribbean, the Taino people called the “mastic” *jocuma* [*acoma*, *acomat*, *coma*, *jacuma*, *jocume*, *tocuma*] (Cuba, Haiti, Dominican Republic, Guadeloupe, Trinidad). Because that language died along with most of these people, spelling variants occur in literature from the 1500s and 1600s. Moreover, people speaking modern languages have their own variations. People now call the trees *jocuma amarilla* (yellow *jocuma*, Cuba), *jocuma blanca* (white *jocuma*, Cuba), *jocuma lechera* (milky *jocuma*, Cuba), or *jocuma prieta* (black *jocuma*, Cuba). Sometimes *jocuma amarilla* is rendered *tocuma amarillo* (yellow *jocuma*). In French, they are *acoma bâtard* (false *jocuma*, Guadeloupe), *acoma franc* (free *jocuma*, Guadeloupe), *acouma jaune* (yellow *jocuma*, French Antilles), or *caimite acoma* (*jocuma* resembling *Chrysophyllum cainito*, Dominica). The name in the Dominican Republic has even become *caya* [*calla*] *amarilla* (yellow *caya*, another Taino name for the tree), *caya blanca* (white *jocuma*), and *caya prieta* (black *jocuma*).

Mastic is one of the few plants in the southeastern United States with indigenous names having cognates in the Caribbean (see also discussions under *Ipomoea*: Moonvine and *Smilax*: Green-Brier). These trees are known to the Seminoles as *okó:ma* (Creek) and *okó: mî* (Mikasuki). Surely, those words are etymologically related to *jocuma*.

Hard wood from these trees was prized by historic and prehistoric people. Glades groups made domestic and war tools from the trees (Austin 1980, 1981, 1997). The Seminoles used the wood for mortars, pestles, and food paddles (Sturtevant 1955), and Caribbean people used the wood in cabinets and boats. Traits of the wood have led people to compare them with other prized materials. The mastic is called *tortuga* [*tortugo*] *amarillo* (yellow turtle, Puerto Rico, Panama), *tortugo Colorado* (red turtle, Puerto Rico), *tortugo prieto* (black turtle, Puerto Rico), and *ebano amarillo* (yellow ebony, *Diospyros ebenum*, Cuba). Comparing the wood to turtle shell and ebony is high praise. The thick sapwood is yellow and the heartwood is yellow to orange. Wood is hard, heavy, with a specific gravity of 0.9, strong, and durable. Other names referring to the wood are ironwood (Florida), *sabina* (roan-colored one, Puerto Rico), *sanguinaria* (bloody one, Puerto Rico), sweetwood (applied by 1607, Barbuda), sourwood (applied to *Oxydendrum arboreum* by 1856, Bahamas), and *tabloncillo* (little plank, Puerto Rico).

Cubans use the Taino name *caguaní* [*coguani*], which may be linguistically related to a river in Puerto Rico called *Caguana*. *Ausubo* (Puerto Rico), the Taino name of *Manilkara bidentata*, has been dubiously applied to *S. foetidissimum*.

Fruits are edible in *S. foetidissimum* and the related and similar *S. salicifolium*, and the Seminoles ate both (Sturtevant 1955). Morton (1968) described *S. foetidissimum* as “gummy, acid and sometimes bitter.” I never found them bitter, but the other two descriptors are accurate. In Florida, people also have called them jungleplum and wild olive because of their fruits. Another name mentioning fruits is *abricot des bois* (tree apricot, French Antilles). That designation seems to be comparable to almond, which is applied to *S. salicifolium*. Comparison to the apricot and almond are possibly a corruption of *almástiga*, as in *almendro* (almond, USA, West Indies), *almendrillo* (little almond, Cuba), *almendro silvestre* (wild almond, Cuba), and *almendrón* (false almond, Puerto Rico).

Medicinally, *jocuma* sap has been used to treat hernias (Roig 1945). The Miccosukees considered the *okó:mi* an important ingredient in a medicine for “washing the body” (Sturtevant 1955). Triterpenoid saponins have been isolated from *S. foetidissimum* (Nicolas et al. 1995), and similar chemicals are known from a related species (Jiang et al. 1994). Those compounds may be responsible for the anti-inflammatory action known in the genus (Desmarchelier et al. 1999).

The mainland subspecies (ssp. *gaumeri*) is called *caracolillo* (little snail, Campeche, Quintana Roo), cream tree (Belize), rosewood (Belize), *subul* (black bird, Maya, Yucatan, Belize), and white candlewood (Belize). *Tempixte* [*tempiote*] (from *tempixquitzli*, dribbling on the lips, Náhuatl, Guatemala) is applied to this tree and others in Mexico (Standley 1920–1926, Pennington 1990), and may be a reference to the sticky fruits. This subspecies is protected for its edible fruits (Pennington 1990).

“Bustic” is a better-known name for *S. salicifolium* (willow-leafed) used in English, Dutch, and French. No etymology has been found, but “bu-stic” may be a contraction of “bully-mastic.” Other variants on “bustic” are willow bustic (USA, Puerto Rico) or willow-leaf bustic (Florida). Other English speakers in the Caribbean now call this tree bolletrie witte (white bully-tree, Guyana), bully-tree (Barbados), bullet-tree (Barbados), red bullet (Jamaica), white bull-tree (Jamaica), white bulletwood (Jamaica), and white bully wood (Jamaica). All those names were derived from “bully,” which originally meant “friend” or “kinsman,” a term of endearment since the time of Shakespeare in 1590. Part of that endearment is because the tree gave such a good material to chew.

The Taino name *jocuma* (Cuba) also has been applied to *S. salicifolium*, as in *jocuma blanca* (white *jocuma*, Cuba). Variants of that name are *acomât batârd* (false *acomât*, Guadeloupe), *acomât marron* (wild *acomât*, Haiti), *acomât petite feuille* (little-leaf *acomât*, Guadeloupe), *acomât rouge* (red *acomât*, Haiti), *caya Colorado* (red *caya*, Dominican Republic), and *cuyá* (Cuba). The name also seems to have cognates in one Seminole language with *toca:tí* (Creek), which may be akin to the Taino variant *tocuma*. There is no obvious linguistic relationship with *ahikittscí* (red tree, Mikasuki). However, I have to wonder if that name is not related to Muskogee *vhecetv*, “to look ahead.” Both may allude to scanning the horizon to see if there is a hammock (tree island) or some other item of interest. Another Taino name for the trees is *jaiquí*, which is also applied to *Manilkara jaimiqui* in Hispaniola.

Sap from *S. salicifolium* also was used as chewing gum. The Maya name for *S. salicifolium* still is *sakchum* [*xac-chum*] (*sak*, white, *chum*, trunk, Yucatan, Belize). From this white-trunked tree, they extracted *tsits-ya* [*txitxya*] (slender zapote), which had many of the properties of the chicle zapote (see *Manilkara*: Wild Dilly). It is known that *chicleros*, harvesters of chicle, tapped the latex of *S. salicifolium*, and it was used separately and probably as an adulterant in “true” chicle (Standley and Record 1936).

Other names for *S. salicifolium* are varied. Some compare the species to others, such as black haw (Florida) and wild mespel (*mespel*, medlar, from Latin *mespilus*, *Mespilus germanica*, Puerto Rico). They are even called tough buckthorn (buck, as a male deer, plus thorn, Florida; see also *Rhamnus*). In Spanish, trees are *zapote faisán* or simply *faisán* (pheasant zapote, Campeche, Belize, West Indies) and *zapotillo* (little zapote, Mexico). Those names are comparable to *sapotille marron* (wild zapote tree, Haiti) and *sapotillier marron* (wild zapote tree, Haiti). *Weidenblattrige-diphole* (willow-leaf dipholis, Dutch Antilles) is merely a translation of an old scientific name. Perhaps

*m'panache* (*panaché*, plumed, Haiti) is a descriptive name for the branches, and *jubilla* (little jubilee, Cuba) may refer to the happiness at finding edible fruits.

The remaining names are of obscure meaning and derivation. An old name in Cuba is *Carolina* (from Carolina or Carlos). Presumably, that refers to a person because the species does not grow in the Carolinas. Both *cháchiga* [*chachiga*] (Belize) and *mijico* (Belize) resemble indigenous words, but do not seem to be Mayan. They are perhaps remnants of the Miskito who formerly lived in the region. The name *galimeta*-wood was first used in 1756 in Jamaica. That has also been rendered *galemata*, *gallamenta*, and even *galimetaholz* (German *Holz*, wood), but its origin is dubious. In Peten, Guatemala, and Belize, the trees are *silillon* or *silion de sabano* (savanna chair?, from *silla*?, Spanish), and in Belize they may be silly young. Finally, the Bahamian names *cassada*, *cassada*-wood, and wild *cassada* resemble the Taino *casabé*, whence *cassaba* (*Manihot esculenta*), although any connection is obscure.

Attempts to eat the fruits on either of these species will quickly make it clear why they were associated with mastic and chewing. The taste is pleasant, but there is a tendency to stick the lips together. Large quantities of the fruits also tend to burn the lips of some individuals. So, let the consumer beware.

### *Silphium*

(From Greek *silphion*, the name of some resinous plant, transferred by Linnaeus to this plant)

***Silphium compositum*** (compound, alluding to pinnatifid leaf blades) (= *S. terebinthinaceum*)  
 prairie-burdock  
 [kidney-leaf] rosin-weed [rosinweed]; rosin-plant

In 1776, William Bartram wrote about this rosinweed in West Florida before the species had a name. Bartram ([1791] 1958) gave the use as a chewing gum by Creeks and traders, and this is not recorded elsewhere. He wrote: "the flower stem, which is eight or ten feet in length when standing erect, terminates upwards with a long heavy spike of large golden yellow radiated flowers; the stem is usually seen bowing on one side or the other, occasioned by the weight of the flowers, and many of them are broken, just under the panicle or spike, by their own weight, after storms and heavy rains, which often crack or split the stem, from whence exudes a gummy or resinous substance, which the sun and air harden into semi-pellucid drops or tears of pale amber colour. This resin possesses a very agreeable fragrance and bitterish taste, somewhat like frankincense or turpentine; it is chewed by the Indians and traders, to cleanse their teeth and mouth." The species was not described until 1803 when French visitor and explorer of the eastern United States André Michaux published his *Flora Boreali-Americana* (Flora of North America).

*Silphium* is a genus of 23 species endemic to eastern North America (Mabberley 1997). Several of the species are indicators of prairie vegetation, while others may not be. *Silphium compositum* is similar to *S. laciniatum* in that they both have large basal and reduced cauline leaves. Both also often have pinnately divided leaves, but there are

differences in their ranges. *Silphium compositum* grows from southeastern Virginia and eastern Tennessee to Georgia and Florida. While *S. laciniatum* is primarily a plant of the Great Plains, it grows east to Ohio and Alabama where it overlaps the range of *S. compositum* (Perry 1937, Settle and Fisher 1970, Sweeney 1970, Barkley 1986).

The only use for *S. compositum* other than the one recorded by Bartram was among the Cherokee. These people used rosin-weed as a stimulant for “weakly” females (Hamel and Chiltoskey 1975). Use was probably more widespread because Moerman (1998) found records of three other species among indigenous tribes. *Silphium integrifolium* was used by the Meskwaki; *S. laciniatum* was used by the Dakota, Meskwaki, Omaha, Pawnee, Ponca, and Winnebago; and *S. perfoliatum* was used by the Iroquois, Meskwaki, Ojibwa, Omaha, Ponca, and Winnebago. Moreover, Jones (1936) found “considerable amounts of pieces of chewed or beaten roots” of *S. laciniatum* at the Newt Kash Shelter in Mennifee County, Kentucky. He commented that it had been found at the Ozark Bluff-Dweller site, but it was not included in Gilmore’s (1931) paper.

Names of *S. laciniatum* and information gathered by Gilmore (1919) in the Missouri River region show that it was still being used in the same way that Bartram reported for the Florida species in the 1770s. The Omaha called their species *zha-pa* (*zha*, weed, *pa*, bitter), and *makan-tanga* (big medicine or root). Winnebago said the plant was *shokanwa-hu* (*shokonwa*, gum, *hu*, plant). Especially children gathered the resin from broken stems for chewing gum. This is perhaps what the Chickasaw call *oktaak taakchili*’ (*oktaak*, prairie, *taakchili*’, gum [wax]). Lewis and Elvin-Lewis (1977) suggested that all species of *Silphium* were used by indigenous people to clean their teeth and as chewing gum.

The Pawnee thought that *S. laciniatum* was a *khats-tawas* (*khats*, medicine, *tawas*, rough) and subsequent settlers agreed. Hocking (1997) considered it a strong stimulant, and the root was boiled with mullein (*Verbascum thapsus*) to treat swelling. It seems strange that Porcher (1863), Millspaugh (1892), Ellingwood and Lloyd (1898), Culbreth (1910), and Felter (1922) did not mention the genus.

Two species are included by Duke et al. (2002). They found that *S. perfoliatum* had been considered as alterative, analgesic, antimeic, antispasmodic, diaphoretic, emetic, emmenagogue, restorative, stimulant, and tonic. They consider it not as safe as a cup of coffee. More positive results were noted for *S. laciniatum*, which they gave two plusses. *Silphium laciniatum* has been used as an alterative, antibacterial, antipyretic, antispasmodic, bitter, diaphoretic, diuretic, emetic, expectorant, tonic, and vermifuge.

The only species of *Silphium* that has a variety of chemical studies is *S. perfoliatum*. That species produces two apiose-containing kaempferol triosides, nine flavonoids (El-Sayed et al. 2002), two carterochaetols (Pcolinski et al. 1994), triterpene glycosides (Davidyants et al. 1984, 1985a,b,c, 1986), and watersoluble polysaccharides (Dudkin et al. 1979). Other studies have found inhibitors of trypsin and chymotrypsin in seeds and vegetative parts of *S. perfoliatum* (Konarev et al. 2002), and monoterpenes (alphapinene, beta-pinene, and camphene) in *S. laciniatum* and *S. compositum* (Tooker et al. 2002).

Complex interactions take place between rosinweed and its herbivores. *Silphium* uses the enzyme inhibitors to reduce herbivory by bacteria, fungi, and insects, while male gall wasps *Antistrophus rufus* (Hymenoptera: Cnippidae) alters the chemistry of the plants to enable them to locate females (Tooker et al. 2002). If these interactions occur between plants and other organisms, why should the plants not also be used by humans?

***Simarouba*: Paradise Tree**

(From Carib *simarouba* or Arawak *simaruppa*, or both)

When I first arrived in Florida, I was constantly misspelling two names. The two trees are in different families, but there is a single letter difference between them. The plants are the gumbo limbo (*Bursera simaruba*) and the paradise tree (*Simarouba glauca*). At one point, a reviewer chastized me severely for misspelling the species name of the gumbo limbo, so I learned. The similarity between the generic name *Simarouba* and *Bursera simaruba* is not accidental. The binomials are the result of confusion about plants found in the French Guiana region in the early 1700s.

Early explorers in French Guiana found the Caribs and Arawaks using a medicinal bark; they

***Simarouba glauca*. Drawn by  
P.N.Honychurch.**

wrote its name phonetically as *simarouba*. These medicinal plants first were taken back to Europe about 1713 under that name. Although Europeans did not know its true source, *simarouba* gained a reputation as a wondrous drug.

In the 1750s, Linnaeus had learned the word *simaruba*; yet, he still did not know which plant it was. Linnaeus's confusion caused him to create the name *Pistacia simaruba* for a Caribbean tree. Later, in 1762, he corrected that mistake and coined the name *Bursera simaruba*, when he realized it was not related to *Pistacia*. That same year he named a new genus *Quassia*, but as yet did not know the relationship between it and the true *simarouba*.

It was French explorer, linguist, pharmacist, and botanist Jean Baptiste Christophore Fuseé Aublet who finally sorted out the differences and created the genus *Simarouba* in 1775. Aublet called the trees *S. amara*, and pointed out that they were the medicine long used by indigenous people in French Guiana. The words those indigenous people used for the trees are still extant. In the Guiana region, the plants are *maruba* [*marupa*, *mboera*]

(Brazil, Guyana, Peru) and *simarouba* [*siemaroepa*, *simaruba*, *simarupa*, *semarouba*] (French Guiana, Guyana, Suriname). Lawrence (1951) said the words were Carib, and the OED (1971) cited the *-ba* ending as evidence of that. However, Pittier (1926) was equally confident that the word was Arawakan, and that the correct spelling was *simaruppa*. They were both correct (Klooster et al. 2003).

The trees that Linnaeus named *Quassia* are relatives of *Simarouba*. Indeed, both are in the same family, the Simaroubaceae, although that name was not created until 1811. According to legend, a black slave in Suriname named Graman (=grand-man) Quassi [Quacy, Quasee, Kwasi] discovered the virtues of the roots of the tree about 1730. Edward S. Ayensu in Grimé (1976) suggested that *Quassi* was from Ghanan *Kwesi*, a name given to all males born on Sunday. According to the OED (1971), “Quassi communicated his discovery to C.B. Dahlberg, by whom it was made known to Linnaeus.” Linnaeus named the genus *Quassia* after the African in 1762.

I consider that story a “legend,” because Quassi was a newcomer to the New World. Like many other Africans, he had learned about the plants from indigenous people who had been using them for thousands of years. A professor of medicine and botany at Halle, Kurt Polykarp Joachim Sprengle, in his revision of Linnaeus’s *Systema Vegetabilium* in 1825–1828, moved them all to the genus *Quassia* to create *Q. amara* and *Q. simarouba*. He may have known something that has subsequently been lost. On the other hand, maybe we have rediscovered with molecular data something Sprengle already knew. A recent idea is again to submerge *Simarouba* under *Quassia* (Fernando et al. 1995).

Either way, for now there are two genera distinguished in the Simaroubaceae, *Quassia* and *Simarouba*. Within *Simarouba*, the indigenous plants in the Guianas are *S. amara*, while Florida trees belong to *S. glauca*, a name given by Augustin-Pyramus de Candolle in 1811. The Florida species, *S. glauca*, ranges through the Bahamas, Cuba, Jamaica, Hispaniola, and from Mexico to Panama. Conversely, *S. amara* grows from the Guianas up through Central America and is sympatric with *S. glauca* in southern Mexico. Sorting out identifications and common names for these two trees is not always done by taxonomists, foresters, or people working in the field although they are often different (Franceschinelli et al. 1998). Maybe it does not matter, because both are used in essentially the same ways.

Paradise tree (Florida, Bahamas) is the most paradoxical name given to these trees. Which of the multiple meanings of the word “paradise” was intended by those who coined that name? The word was taken from Old Persian, *pairidaeza*, a park or enclosure, and became *paradeisos* in Greek, and *paradisus* in Latin. The original concept was a garden, a place where plants and animals were well-watered in contrast with the hostile, dry, desert outside. By A.D. 1000, a “paradise” was already considered the abode of God. By A.D. 1300, it was a place on earth being compared to God’s Paradise, and by the 1370s it reverted to the original meaning and applied generally to a garden or pleasure garden. Some have even suggested that the name came into being because the seed kernel contains poisons (Morton 1968b), and eating them would send you to Paradise.

Many of the names compare the fruits to olives, and indeed, both are black when ripe and yield oils that can be used for cooking, manufacturing margarine, or making soap (Morton 1968b, Chavelas-P. 1981, Lognay et al. 1981a, b, Satpathi 1984, Jeyarani and Reddy 2001). Some names making this comparison are *aceitillo* (Puerto Rico), *aceituno* [*aceituna*] (olive tree, Chiapas, Honduras, Nicaragua, El Salvador, Belize, Costa Rica,

Panama), *aceituno negrito* (black olive tree, Nicaragua), *manteco* (butter), and *olivo* (olive, Chiapas, Costa Rica).

Mostly, however, the names allude to the bitter taste that led to medical applications. Sometimes the tree is just *amargo* (bitter, Venezuela). More often it is bitter damson (Jamaica), mountain damson (English Antilles), bitter ash (Dominican Republic), bitterwood (English Antilles), *bois amer* (bitter wood, Haiti), *palo amargo* (bitter wood, Dominican Republic), *quassia amarga* (bitter quassia, Dominican Republic), *quinquina d'Europe* (European quinine, Haiti), or *simarouba* [*siemaroepa*, *simaruba*, *simarupa*, *semarouba*] (Costa Rica, Cuba). Other names alluding to medicinal use are *bois négresse* (black woman's tree, Haiti), dysentery bark (Belize), *Juan primero* (the first John), and *negrito* (little black one, Mexico, Belize, Honduras, Nicaragua). Perhaps some of the other names make similar allusions, but they are more obscure. These include *bois cayan* (tree from Cayenne, French Antilles), *chapascuapul* (maybe Náhuatl, Mexico), *gavilán* (hawk, Cuba), *jucunuco* (El Salvador), *lagartillo* (little alligator, Costa Rica), and *pujilté* [*pajulilte*] (Chiapas).

The undersides of the leaflets give a decided white glint when they are buffeted by winds and contrast pleasingly with the dark green upper surfaces. That difference may have led to names such as *bois blanc* (white wood, Haiti), *palo blanco* (white tree, Cuba), and *xpaxakil* [*pac*, *paque*, *pasa*, *pa-sac*, *pa-sak*, *pasaak*, *pa'sa'ak'*, *pasac*, *pasaque*, *pzaque*, *pask'*, *x-pak*, *x-pak'il*, *x-pasak'il*, *xpazakil*] (*sak*, white, *pa*, something thrown away, Maya, Yucatan, Belize, Guatemala). The Mayan name is applied because mature fruits give off a disagreeable odor. Incredibly, in spite of that odor, the pulp of the fruits is still eaten by people everywhere.

Several of the names compare the trees with others, often those in temperate regions. For example, it is *bois frêne* (ash tree, Haiti), *frêne* (ash, Haiti), and *roblecillo* (little oak, Cuba). Still, there are parallels within the tropics. There the tree is sometimes called *daguilla* [*daguillo*] (comparing with *Lagetta lagetto*, Thymeliaceae, Dominican Republic). However, that use is more complicated because the same name is given to *Philodendron* and *Yucca*, probably because each has useful fibers. In Guatemala, *Simarouba* is *jocote de mico* (monkey's plum, Guatemala), which highlights a similarity to *Spondias mombin* (Anacardiaceae). In Mexico, it is *rabo de largarto blanco* (white lizard's tail, Oaxaca), which notes that the leaves are similar to *rabo de largarto* (*Acacia paniculata*, Fabaceae).

One name, stavewood (Jamaica), notes the use of the wood, which is white-yellow or somewhat purplish, bitter, fine, smooth, has a specific gravity of 0.40, and easily worked but not durable. Apparently, the wood lasts long enough for staves in barrels. The high tannin content resulted in the name *zapatero* (shoemaker, Mexico), and that compound has been extracted for tanning leather in many areas (Hocking 1997).

A variety of triterpenes, quassinoid glucosides, and lipids in the bark and root are bitter and astringent, and have been used as an amebicide against *Entamoeba histolitica*, as an analgesic, to treat anemia, as an antibacterial, antimicrobial, antileukemic, antimalarial, antirheumatic agent, against chronic dysentery, diarrhea, diarrhea with colic, dyspepsia, as an emmenagogue, to control excessive menstruation, fevers, gonorrhea, hemorrhage, internal bleeding, sores, and as a stomachic, sudorific, and vermifuge (Standley 1920–1926, Spencer et al. 1947, Martínez 1969, Liogier 1974, O'Neill et al. 1988, Wright et al. 1988, Cáceres et al. 1990, Arvigo and Balick 1993, Franssen et al.

1997, rain-tree.com 2002). Fruits in El Salvador are made into a liqueur esteemed for stomach problems (Martínez 1969). However, in large doses extracts are purgative and vomative (Liogier 1974). In addition, compounds from *Simarouba amara* have been shown to be cytotoxic and antineoplastic (Polonsky et al. 1978, Bhatnagar et al. 1984).

The number of uses to which people have put these trees is staggering. Perhaps that is why they gave them the name Paradise tree—they are so useful, they must be from Paradise.

### *Sisyrinchium*

(Theophrastus, 372–287 B.C., used the Greek *sisyrinchium*, based on *sys*, pig, *rhynchos*, snout, for what later authors called *Gynandris sisyrinchium*, a plant related to *Iris*; Linnaeus reapplied the name to American herbs)

*Binsenlilie* (rush lily, German)

blue-eyed grass (the yellow center on the blue flower has been referred to as an “eye” since classical Roman times, when it was *ocellus* in Latin; however, the name is doubly incorrect, as Diggs et al. 1999 and earlier authors have pointed out—the plants have a yellow eye, not blue, and are not grasses; perhaps we should write it “blue eyed-grass”)

*purole* (Coahuila)

*sisyrinchium* (French)

*Sisyrinchium angustifolium* (narrow-leaved)

batchelor’s-button (Massachusetts)

Bermuda-flag; *bermudienne* (from Bermuda, Quebec; this is based on a comparison with *S. bermudiana*)

blue-eyed lily [Mary]; blue-grass [bluegrass] (Massachusetts); pointed blue-eyed-grass

forget-me-not (typically applied to *Myosotis*, Boraginaceae, a plant that also has a blue corolla limb and yellow eye, Maine)

grass-flower (Massachusetts)

*Grasschwertel schmalblättriges* (small-leaved sword-grass, German)

pig-root [pigroot] (used in English by the 1890s, but surely older; perhaps simply a translation of *sisyrinchium*)

rush-lily

satin-flower [-lily]

Spanish nut (first in Gerarde’s *Herball* [1597] 1975, for a different member of the Iridaceae) star-eyed-grass [stargrass] (Massachusetts)

*Sisyrinchium nashii* (named for George V. Nash, 1864–1921, agrostologist and head gardener at the New York Botanical Garden)

*cikto ika aha:ka*: (*cikto*, snake, *ika*, head, *vhaketv*, resembling, Creek); *cintyó:sá:bî* (snake’s head replica, Mikasuki)

*coló:ntkî* (Mikasuki)

Back in the early 1970s, I ventured to study *Sisyrinchium* with my friend and colleague Royce L. Oliver (1929–1997). He had been working on the genus for years, and thought that we might solve one of the taxonomic problems for the Florida species. Eventually, we published our results, with which no other systematists in the world have agreed (Austin and Oliver 1974). In spite of other botanists' insistence on lumping *S. solstitiale* under the name *S. xerophyllum*, none of our colleagues has ever been able to explain how it is that a species that blooms in the spring (*S. xerophyllum*) is able to maintain a single gene pool with fall-flowering plants (*S. solstitiale*). If they are genetically isolated by different flowering seasons, how can they be the same? Dan Ward (personal communication, Oct. 2003) has finally agreed with our conclusion of two species, but tells me that we erred in using the name *S. solstitiale*. The fall-flowering plants have no species name.

I found many aspects of the morphology, and hence the taxonomy of the group, to be based on environmentally influenced aspects, especially fires. Given the disagreement on the limits of species, it is not surprising that *S. angustifolium* and *S. albidum* have been considered conspecific with each other and two more named species (Diggs et al. 1999). Different aspects of the genus, like pollination, habitat preference, and association with humans are fascinating. Records exist for all species, except the endemic *S. xerophyllum*, having been used by indigenous people. The restricted range of *S. xerophyllum* in peninsular Florida and the quick extirpation of native people in that area after European arrival probably explain its absence from the records.

There are perhaps 80 species in *Sisyrinchium*. Kartesz (1994) listed 38 in North America, and the rest are in Central and South America. Because the genus was entirely native in the New World, Europeans largely compared the herbs with plants they knew at home. Mabberley (1997) thought that *S. bermudiana* might be native to the Old World, because it occurred in Ireland. However, the only other place in the world that it occurs is Bermuda, and Dan Ward (personal communication 2003) tells me that that the Irish plants are actually *S. angustifolium*.

John Gerarde's ([1597] 1975) *Herball* includes the entry: "Spanish-nut hath smal grassie leaues." He further wrote, "The Spanish nut is eaten at the tables of rich and delicious, nay vicious persons, in sallads or otherwise, to procure lust and lecherie." Some have thought that was a *Sisyrinchium*, but it apparently refers to an African plant. John C. Loudon's *An Encyclopedia of Plants* published in 1829 attaches the name *Gynandriris sisyrinchium* (as *Moraea*) with the common name Spanish-nut. *Gynandriris* is an African genus.

Outside Florida, the Menomini of Wisconsin mixed *S. albidum* with horse food to make the animal sleek, vicious, and to give it a poisonous bite (Moerman 1998). They also kept a plant in the house or pocket to ward off snakes.

*Sisyrinchium angustifolium* was mixed with other greens and eaten by the Cherokee (Moerman 1998). Considering the other uses, that application blurs the distinction between medicine and food. The Cherokee also gave an infusion of the root to children to control diarrhea. The Iroquois of New England used it to relieve constipation and diarrhea (Moerman 1998). *Sisyrinchium nashii* was used by the Mikasuki as an analgesic, and for "Moving Sickness," with symptoms including pain moving in the region of the waist (Sturtevant 1955).

Several other species were used by different tribes in North America, and at least one species is used in Venezuela (Morton 1981, Moerman 1998). Most *Sisyrinchium* are considered laxative, and some, like *S. albidum*, are considered poisonous. Cronquist (1981) noted that many members of the family often have long, prismatic crystals of calcium oxalate, are sometimes poisonous, and have terpenoids, the glycoxanthone mangiferin, and naphthaquinones or anthraquinones, and are occasionally cyanogenic. The calcium oxalate alone would account for the reputation of being “poisonous” because of the burning sensation they cause on ingestion. Some of the other compounds are known laxatives, especially anthraquinones (see *Rhamnus*).

### *Sium*

(From Greek *sion*, the name of some marsh plant)

*berle* (from Latin *berula*, of Celtic origin; akin to the Gallois *berwr*, fountain cress, or old Provençal, *berla*, or Spanish *berro*, cress; still in use in the countryside, but more often replaced by the modern *cresson*, French)

*erba cannella* (cinnamon herb, Italian)

*Merk* (German)

### *Sium suave* (sweet)

*berle douce* (sweet cress, Quebec)

*fo:similpá* (*fo:si*, bird, *im*, its, *ilpá*, food, Koasati) hemlock (of obscure etymology, but from Old English *hymlice*, feminine, and *hymlic* masculine, from about A.D. 700; no cognates in other languages; originally applied to *Cicuta*); hemlock-water-parsnip [hemlock waterparsnip]

*hlue tla<sup>h</sup>le<sup>h</sup>* (Slave, Canada)

*queue de rat* (rat’s tail, Quebec)

*siwaskatask* (sweet carrot, Cree); *uskotask* (Plains Cree)

water-parsnip (comparison to the original “parsnip,” from Middle English *passenep*, in turn from Latin *pastinaca*; the Latin is from *pastinare*, to dig and trench the ground, and *pastinum*, a twopronged digging fork)

When the Spanish arrived in the New World, they were already familiar with *Sium*. One species, *S. latifolium*, is native to the Mediterranean from Spain eastward (*Flora Europaea* 2003). At least people in Italy cooked the leaves and ate them (Hedrick 1919). As the New World was beginning to be known, a second species called “skirret” was introduced into Europe. That herb, *S. siarum*, is native to Eurasia from Bulgaria, Hungary, and Romania eastward. From its region of nativity, the plants reached England some time after 1538 but before 1548 (Hedrick 1919). John Gerarde commented on skirret in his *Herball* in 1597, and by then the species was in demand as far north as England for its edible roots (Austin 2002).

By the 1750s, Linnaeus was familiar with both European species and some elsewhere (Linnaeus [1753] 1957). If the American plants had been discovered by that time, he did not know them. Indeed, it was 1788 when Thomas Walter described *S. suave* in his *Flora Caroliniana*. It seems likely that people familiar with European plants took this American native to be the Old World skirret. However, in the absence of preserved herbarium material, that will never be substantiated. It is known that the settlers were cultivating a remarkable number of European root crops by the 1700s. For example, in the 1760s, Bernard Romans found skirret in Mobile, Alabama (Romans [1775] 1961). Skirret was being grown there with other Old World root crops, including carrots (*Daucus carota*), turnips (*Brassica rapa*), radishes (*Raphanus sativus*), leeks (*Allium porrum*), and scallions (*Allium cepa*).

Sir John Richardson wrote in 1852 that, from the Ojibwa, “who were encamped on the Otter Lake, we procured a quantity of small white root, about the thickness of a goose quill, which had an agreeable nutty flavor. I ascertained that it was the root of the *Sium lineare* [= *S. suave*]. The poisonous roots of *Cicuta*...are often mistaken for the edible one, and have proved fatal to several laborers in the [Hudson Bay] Company’s service. The natives distinguish the proper kind by the last year’s stem, which has the rays of its umbel ribbed or angled, while the *Cicutae* have round and smooth flower-stalks” (Richardson in Fernald et al. 1958).

Several indigenous tribes used *Sium* as food (Moerman 1998). The Algonquin, Cree, and Ojibwa are among the northeastern tribes that ate the roots. However, a number of more distant people in the western and northwestern United States also ate them. These tribes include the Bella Coola, Carrier, Klamath, Montana, Okanagan-Coville, Shuswap, Slave, and Thompson.

There are a few records of people using the herbs in medicine or magic (Moerman 1998). The Iroquois made a poultice of mashed roots to relieve pain in broken or dislocated limbs and sprained muscles, and made a decoction for treating people suffering from epilepsy. The Dakota used the roots to sooth stomachache. The Shuswap thought the flowers were poisonous, although they ate the roots. The Ojibwa smoked the seeds to drive away and blind the evil spirit that steals one’s hunting luck.

Records vary about whether or not the plants are poisonous, even among tribes that used them as food. Some considered part of the plant poisonous, while the root was thought to be edible. Turner (1978) has found them eaten by indigenous people in British Columbia. Turner and Szczawinski (1991) and Diggs et al. (1999) found records of the herb poisoning livestock. Similarly, *S. latifolium* is considered poisonous to livestock in Europe (Polunin 1969), but eaten by people (Hedrick 1919). Maybe the different plant parts contain distinctive chemicals, or people and animals react to them differently. Indeed, Hocking (1997) says that the flowers are poisonous, while the young leaves, stems, and roots are edible when cooked.

Perhaps the problem is that the herbs are so similar to water hemlock (*Cicuta maculata*) that they have been mistaken for them. For the related *S. siarum*, Duke et al. (2002) suggest that the only danger in using the herb is confusion with poisonous members of the Apiaceae.

***Smilax*: Green-Brier**

(Greek *smilax*, *smilakos*, a twining plant; the Latin *smilax* was used by Pliny, A.D. 23–79, for what is now *Smilax aspera*, but he also applied it to the yew and an evergreen oak)

Shortly after we moved into our Florida home, birds perched on the Spanish bayonet (*Yucca aloifolia*) and false sisal (*Agave decipiens*) in our front-yard xeric garden and “planted” a green-brier (*Smilax auriculata*). After we had torn out the climbing stems dozens of times, my wife, Sandra, decided that she was going to “eliminate” the pesky vine and began digging up the rhizomes. After a long work session, she had over a bushel of the woody horizontal stems. A few days later the stems were weaving themselves into their spiny supports, and it was as if she had done nothing. At least, I had taken a picture of the rhizomes to use in teaching classes, and I had an entertaining story to tell students.

Europeans already knew *Smilax* when they came to the New World. The species they knew best was *S. aspera*, which is a southern European plant native from Portugal to Yugoslavia. Plants were cultivated as far north as Germany during Leonard Fuchs’s time in the mid-16th century (Meyer et al. 1999). Europeans called this plant sharpe smilax (English 1568), *grosz stechend Windt* (big spiny vine, German 1542), *sharpff Windt* (sharp spiny vine, German 1542), *groote stekende wranghe* (big spiny vine, Dutch 1549), *smilax picquant* (spiny smilax, French 1549), and *smilace aspra* (spiny smilax, Italian 1551). Speakers of Arabic called it *’ushba* (herb) or *’ulliq* or *’ullayk* (generally applied to *Rubus*, Rosaceae). People speaking Spanish called the climbers *zarzaparilla* (*zarza*, brier, *parilla*, small grape vine), and that became the source of the English word “sasparilla.”

Cowboy movie stars Roy Rogers and Gene Autry were popular in the 1940s and 1950s. They usually played a scene in each movie where the indestructible hero walked into a saloon full of bad guys and ordered a bottle of “sasparilla.” Sometimes a fight ensued where the single good guy outgunned a dozen or so criminals without bloodshed—not a bad feat with guns that held only six bullets.

At the time, I had no idea what “sasparilla” was, but it obviously was not a drink preferred by the toughs. Later I learned that the same basic ingredient in “sasparilla” was the basis of “root beer.” At the time, “A&W Rootbeer” businesses were common in rural towns. Both “sarsaparilla” and “root beer” came from the genus *Smilax*, and had a long history as a tonic drink in Europe before the New World was discovered. Early American settlers made root beer from *Smilax* rhizomes by combining them with molasses and parched corn, and then allowing the brew to ferment (Morton 1968b). That formulation was essentially unchanged during the Civil War when Confederate soldiers made the same drink (Porcher 1863).

Not only was the native European *S. aspera* used, but from 1535 onward, people knew of the “China root” or simply “China,” another species now called *S. china* (Linnaeus [1753] 1957). Some other early names were *Radix China* (China root, Latin), *tuber chine* (China root, French), and *chob-chini* (China root, Persian). In Portuguese, it was “*alguma raiz ou pão de China*” (some root or bread from China), cited by Garcia de Orta in 1563. These rhizomes are now known to contain steroidal sapogenins, and the glycosides of the steroids smilagenin and sarsasapogenin (Itoh et al. 1977, Lewis and Elvin-Lewis 1977, Foster and Duke 1990) that were the basis of the tonics.

The Asian species was considered an “infallible remedy for gout” (OED 1971). Gerarde ([1597] 1975) wrote that the “China” was used “to cure the French Pox.” Culpeper (1653) prescribed medicinal preparations from *Smilax* to be used to neutralize poisons, and to serve as a diuretic, an eyewash, against colds, to stop flatulence, sores, and venereal disease, and to serve as a tonic. Hocking (1997) expanded that to say that the rhizomes contain tannins, gums, resins, smilax saponins, coloring matter, and starch, and were used as *Radix Chinae ponderosae* to treat gout, syphilis, frambesia (a venereal disease), as an antidote in mercury poisoning, and as an aphrodisiac.

When they arrived in the New World, Europeans were delighted to discover more kinds of *Smilax*. In

***Smilax*.** *Smilax auriculata* (top left). Drawn by P.N.Honychurch. *Smilax bona-nox* (top right). Drawn by P.N.Honychurch. *Smilax glauca* (lower left). From Britton and Brown 1896.

*Smilax laurifolia* (lower right), a. Segment of stem showing thorns and tendrils, b. Branch with clusters of flowers, c. Cluster of flowers, d. Staminate flower, e. Branch with fruits. Drawn by Vivian Frazier. From Correll and Correll 1972.

Frampton's ([1577] 1925) translation, the Spaniard Nicholas Monardes says that a merchant "shewed to mee a greate Roote, and other little rootes, and he asked mee what rootes they were, I aunswered that they were Rootes of the China." He added, "the Indians be healed of grevous diseases. And so they have it in great estimation, they doe heale al manner of large diseases therewith: and also the sharpe diseases: especially Agues with the Water of it, provokyn Swets, and by this waie they heale many." Near the same time, Thomas Harriot ([1590] 1972) wrote that plants in North Carolina were like "The China root brought from the East Indies."

The name "China root" became so entrenched in English that it was applied to most *Smilax* species. In the Bahamas *S. auriculata* is China-brier. *Smilax glauca*, *S. bona-nox*, *S. havanensis*, *S. laurifolia*, and *S. tamnoides* may be *bejuco chino* (China vine, Cuba), China-brier [chainey brier, chaney-brier] (Carolinas, Florida, Bahamas), China-root (USA), or *raiz de China* (Cuba). In more tropical areas, *S. havanensis* is China-briar, but it is also called chaney-winder, chaney-wine, and chaney-vine (USA, Bahamas), all variations of the same name. The same species is *liane siguine* (Haiti), where "seguine" is probably a corruption of "China." Sometimes it is just *siguine* [*tsiguine*] (Haiti). Those seem to be variants of *bois d'eschine* (China root, French) from the 1500s. All the species of *Smilax* in Nicaragua are called chaney root (Creole), China root, *chiny* (Miskito), but they are also *cuculmeca* (*cuculá* is said to be Quechua for a dove, Spanish), *salhalai* (Sumu), and *wasalanka* (Sumu).

"Brier" in the names is an English word of unknown origin, already in use about A.D. 1000, and occurring as *bráer* (West Saxon), *brér* (Anglican), and *brere* (Middle English). In all of these, it was a prickly, thorny shrub or bush, often confined to the wild rose (*Rosa*) or blackberries (*Rubus*). Only later was "brier" applied to other thorny plants such as *Smilax*.

We know only the name in Timucua, which Crawford (1988) gave as *hassez*. He thought it referred to *Zamia*, but the fact that historical documents recorded that it was "roots from which they make their bread" argues against that. There were never enough *Zamia* in the northern part of the peninsula to support many people. Besides, it was *Smilax* that was the mainstay of southeastern tribes.

Florida has 12 species of *Smilax* (Wunderlin 1998), and all were probably used similarly. Some common names are applied indiscriminately. As catbriers (USA) or sawbriers (Florida, Bahamas) they scratch; as squirrel-briers (USA) they climb; as bullbrier (USA) and horse-brier (USA) they have stout growth. The concept of prickly climbers is not confined to English, and they are *bakcî* (brier, Mikasuki) and *kvco* (Creek, Muskogee) to the Seminoles. The Alabama said *bakcho* (thorny brier), the Koasati *bakcô*, and the Choctaw *bisakchakina* (*bissa*, blackberry). *Smilax auriculata* is known to the Seminoles

as *cintalô:simbakci* (black-snake brier, Mika-suki) and *ciktolastocikinkacô* (*getto*, snake, *Ivste*, black, *-uce*, little, *em*, its, *kvco*, brier, Creek). Alabama speakers said *bakcho hollo* (*bakcho*, brier, *hollo*, evil) or *bakchokchako* (*bakcho*, brier, *okchakko*, blue). *Kvco lâne* (*kvco*, brier, *lâne*, yellow) is the name among the Muskogee speakers in Oklahoma. The Osage said *wa-xa'-ga tu-hu* (*wa-xa'-ga*, prickly, *to-ho*, green). The Koasati named three species—*kontí* (*S. bona-nox*), *bakcô ok:cakkô* (*bakcô*, briar, *okcakkô*, green, *S. rotundifolia*?), and *bakcohollô* (*bakcô*, briar, *hollô*, taboo, *S. walteri*).

The same ideas are found in other American names and in Old World languages. To ancient people in the Middle East, *Smilax* was *melu* (ascent, as in climbing, Akkadian). However, the cognate word *mula* (Sanskrit) notes the edible rhizome. That view is related to Seminole *a:hi* (root, Mikasuki), and their relatives the Choctaw say *ahe*. Probably, the Biloxi *ato' [ado']* is cognate. Usually, however, when the Seminoles refer to these rhizomes they say *kunti [kantik, kontik]*. The Seminoles call the rhizomes of several *Smilax* species *kunti chate [conti chatee, coontie chabi, coonti chacli, coonti chatee]* (*kunte*, root, *cate*, red, Creek), which is sometimes translated as “red flour” (Speck 1941, Sturtevant 1955). Related words are *kanta* (Alabama), *kantâk [cantaque]* (Houma), *kantak* (Chickasaw, Choctaw), *kontí* (Koasati), and *kûnte* (Muskogee). Indeed, in the Muskogean languages, the names refer to a starch extracted from the rhizomes. The Choctaw even have the preparation *kantak paska* (*smilax* bread), making it from *kunshak ahe* (reed potatoes). Koasati called the bread *kontí tabáhka*. Although their language was not related, the Biloxi called the plant *atuti'* (*ato'*, potato, *uti'*, stem or plant) and the flour from them *atudi' nupxi'* (root meal).

In an unrelated Algonquian language, rhizomes are *tsinaw* (North Carolina, Harriot [1590] 1972), which indicates their widespread importance as a starch source, although Geary (1955) took that word to be their pronunciation of English “China.” Perhaps the Powhatan word *cawindgus*, “bramble or briar,” belongs here. All that is certain is that the cognate word in Delaware was *kawinsi*, thorn (Siebert 1975). While Siebert (1975) did not mention the Carolina Algonquian name, it seems to be cognate with both Powhatan and Delaware. The Ontario Delaware *nzúkii-lehlookihláashak* (*nzúkeew*, black, *lehlookihlaash*, raspberry) for the black raspberry does not seem to be cognate (O'Meara 1996). Choctaw *shinuk yolulli* (*shinuk*, sand, *yolulli*=?) seems to be unique.

*Smilax* rhizomes were a source of starch for various indigenous groups of the South Atlantic States (Morton 1981). In addition to the Seminoles, indigenous people eating the starch or rhizomes included the Algonquians of coastal North Carolina (Harriot [1590] 1972), the Biloxi (Dorsey and Swanton 1912), Choctaw (Bushnell 1909), Cherokee (Hamel and Chiltoskey 1975), Houma (Speck 1941), and Glades and Timucua people (Austin 1980, Hahn 1986). That same notation of edible rhizomes is made with *bejuco [de] ñamé* (yam vine, Cuba) and *ñamé cimarrón* (wild yam) for *S. havanensis*. Both Cuban names compare the plants with the true yam, *Dioscorea*. Although he does not indicate the people using them in Alabama, Hocking (1997) noted that *S. pumila* and *S. smallii* rhizomes also were food plants there.

Preparation to make the rhizomes edible is said to be simple or complex depending on age. When rhizomes are young and tender, they can be cooked and eaten (Morton 1968b). Harriot ([1590] 1972) reported: “From these roots while they be new or fresh beeing chopt into small pieces & stampt, is strained with water a juice that maketh bread, & also being boiled, a very good spoonmeate in maner of gelly, and is much better in tast

if it be temperd with oyle.” Among other people, the mature rhizomes were chopped, pounded with a mortar and pestle, mixed with water, and strained. The sediment became a fine, reddish meal when dry; it took about 50 pounds of rhizomes to make 5 pounds of flour. A small amount of flour with warm water and honey became a reddish jelly. The meal, mixed with corn flour, was fried in bear grease to make hot cakes or fritters (Morton 1968b).

Williams ([1837] 1962) described the Seminole method of using *Smilax*, which he called “China briar.” He wrote: “The Indians grate them, or bruise them in a large wooden mortar, then throw on water, strain the starch through baskets, dry and pulverize it; the color is reddish brown. They mix it with a fine homony, and make cakes; with honey and warm water, it becomes a fine jelly; toasted and mixed with sweet milk, it is a delicious food.” The Seminoles called their preparation *sáfki* [*sofkee*, *sofkey*], which the Choctaw call *tanfula* and the Cherokees call *ganoheni* (Hudson 1976). We call the preparation “grits” (ground hominy) and make it from corn (*Zea mays*, which see), as they also did, without the *Smilax*.

Several different species are green-brier (Florida, Bahamas, Puerto Rico). Sometimes there are variants on the name to denote individual species such as laurel-leaved green-brier (*S. laurifolia*, Carolinas) and prickly greenbrier (*S. havanensis*, Florida, Bahamas). For obscure reasons, these climbers are also called wild bamboo (Florida) or bamboo [vine] (Florida, Carolinas).

One of the most widespread and commonly used species is *S. bona-nox*. The name was taken from *buenas noches* (good night) applied to the species in the Spanish West Indies and recorded by Charles de l’Escluse because of fragrant nocturnal blossoms. Due to its armament, that plant has been called blasphemevine (Florida, Carolinas), hellfetter (USA), and tramp’s trouble (Florida, USA). The Natchez, distant relatives of the Seminoles, call the plant *we-bula*. At least as common and popular with the Seminoles was *S. laurifolia*, which they call *co inkontí:kacô* (*eco*, deer, *em*, its, *kunte*, root, *kvco*, briar, Creek) and *i:cinkantikí* [*iicinkantik*] (deer’s root, Mikasuki), because deer eat rhizomes and sprouts (Sturtevant 1955).

Although there are no records of indigenous people eating the young stem tips, people of European ancestry eat them. These people compare them with other edible Old World plants by calling them wild asparagus (Carolinas) or wild spinach (Carolinas). The young stems are tender and succulent, and may be eaten raw or cooked. There is, however, considerable variation and some are bitter when raw, probably due to tannin concentration (Hocking 1997). Students always loved to see me react when I sampled them in the field and got a particularly bitter one.

Fruits of *Smilax* were eaten by the Meskwaki (Smith 1928), Omaha (Gilmore 1913), and probably many other people. One name used for several species of *Smilax* in Texas is “stretch-berry,” ostensibly because of the rubbery texture of fruits (Tull 1999). Fruits of some species are considered inedible, such as of *S. bona-nox*, while others like *S. lasioneuron* (in literature as *S. herbacea*) are eaten.

Perhaps secondary to food, native Americans used the rhizomes to obtain dyes. A red-pink dye may be extracted by crushing the rhizomes in water and then soaking the skin, or simply by holding the skins over smoke from burning roots (Bennett 1997). This coloring source is favored because it helps the hides repel rain. Berries of most species supply dyes of blue, violet, and purple (Coon 1974, Tull 1999).

Like people in other parts of the world, indigenous groups in the southeastern United States made a variety of medicines with *Smilax*. Sturtevant (1955) reported that the Seminoles used *S. laurifolia* and *S. auriculata* to treat chronic sicknesses and in birth ceremonies, although Alice Micco Snow seems no longer to use either (Snow and Stans 2001). Sometimes *Smilax* medicine was used alone for chronic problems, and at other times, it was mixed with many other plants. The Cherokee made medicine from stem bark for burns and skin problems, and made rhizomes into a tonic (Hamel and Chiltoskey 1975). The Choctaw also made a tonic from the rhizomes (Bushnell 1909). Indigenous people in the Carolinas used a root infusion of *S. bona-nox* to “mundify and sweeten the blood” and to treat scurvy, fever, gonorrhea, and syphilis (Vogel 1970). The Houma used the root bark for urinary infections (Speck 1941). Hocking (1997) recorded people in Alabama using *S. pumila* and *S. smallii* to treat rheumatism, as an alterative, and as an aphrodisiac.

It is well known that numerous *Smilax* species contain steroidal sapogenins (Okanishi et al. 1965, Jia and Ju 1992, Kubo et al. 1992, Sashida et al. 1992, Ju and Jia 1993, Ju et al. 1993, 1994, Bernardo et al. 1996, Santos et al. 1997). Several other types of bioactive compounds also have been isolated, including flavanones (Chen et al. 1999), glycosides (Ju and Jia 1993, Li et al. 1996, Chen et al. 1996, 2000), isoflavones (Yi et al. 1998), and phenolics (Li et al. 2002).

In addition to being a tonic, *Smilax* has also been shown in laboratory studies to be antirheumatic (Ageel et al. 1989), antimutagenic and mutagenic (Lee and Lin 1988, de Sa Ferreira and Ferrão Vargas 1999), to treat gastrointestinal disorders (Cáceres 1990), and hypoglycemia (Fukunaga et al. 1997), and to heal skin infections (Cáceres et al. 1991). There is evidence that *Smilax* may be effective in free radical scavenging, antioxidant enzyme fortifying (Lee et al. 2001), and even in partial neutralization of the hemorrhagic effect of snakebite (Castro et al. 1999). Many of these experimental results support the historical use of the genus in medicines.

The name *Smilax* was originally recorded by Pliny, A.D. 23–79, in the 1st century A.D. He applied the classical Greek name (*smilakos*) to *S. aspera*. However, in Greek mythology *Smilax* was also a nymph who fell in love with mortal Krokos. It was a hopeless passion, so the gods changed her into the twining herb (Baumann 1993). Perhaps the analogy is good because the nymph lives on to help and bother humans. At least she bothered my wife and me for three decades in our front-yard garden.

### ***Solanum*: Nightshades**

(From Latin *solamen*, a comfort, or *sol solis*, the sun)

When Leonard Fuchs published his *Great Herbal* in 1542, he knew of eight plants we now place in the Solanaceae. Of those, five were native to Europe. The others had been imported by explorers in the Americas and Asia. Two of the native species in Fuchs’s time were known as “nightshades” by speakers of English—*Atropa belladonna* (deadly nightshade, nyghte shad) and *Solanum nigrum* (black nightshade). Only the *Solanum* was a “nightshade” to speakers of other languages.

Beginning some time before A.D. 1000, speakers of English began calling certain European plants the “nightshades.” Speakers of other Germanic languages called them

the same with *nihtscada* (Old English), *nachtschade* (Dutch), *natskade* (Danish), *nattskatta* (Swedish), and *Nachtschatten* (German). All of those names include the word “night” and “shade,” apparently alluding to the poisonous berries although no one is certain of the original reference. Perhaps it was a reference to death and ghosts.

***Solanum*.** *Solanum bahamense* (left). Drawn by P.N.Honychurch. *Solanum erianthum* (right), a. Fruiting branch, b. Flowering branch, c. Trichome from the leaf. d. Flower, side view. e. Flower, longitudinally dissected, f. Stamens enlarged, g. Floral diagram. Drawn by Priscilla Fawcett From Correll and Correll 1982.

Maybe the name “nightshade” was originally applied to *Solanum* in England, and then also given to *Atropa* as a more potent representative. Either way, plants in the family were so famous as poisons that New World members were suspect when they were first introduced.

*Solanum* is an ancient name for a European plant, and many think it was originally *S. nigrum*. The origin of *Solanum* is uncertain. One school contends that it is derived from *solamen*, a comfort, an allusion to the soothing properties of the plant. The related word in Akkadian *sululu* means happy, glad. Others, however, think that it came from Latin *sol*, *solis*, sun. That interpretation would be more consistent with the 16th-century pharmaceutical name *solatrum* and the Italian *solatro hortolano*. Moreover, the plants are

heliophiles, and their yellow stamens surrounded by white petals might be viewed as miniature suns. While we may never know the correct etymology, it was just like Linnaeus to continue usage of a name that has multiple interpretations.

Although Fuchs did not mention the second species, there were two *Solanum* species familiar to Europeans, *S. nigrum* (black nightshade) and *S. dulcamara* (bittersweet). Fruits of bittersweet were woven into the collar of Egypt's Tutankhamun's third coffin, so both were long part of the pharmacopoeia of Eurasians (Manniche 1989).

Other Europeans made no reference to the poisonous nature of the *Solanum*, with the French saying *morelle* (little blackberry), a name evident in the 16th-century English names "petimorel" and "morel." The Spanish of the time said it was the *yerba mora de los huertos* (blackberry herb of gardens).

When Europeans arrived in the New World, they found an array of "nightshades" that were new to them. They also found that the people in the Americas used those new species in many ways. Some of the "nightshades" that were new to Europeans were tobacco (*Nicotiana tabacum*), potato (*S. tuberosum*), and tomatoes (*Lycopersicon esculentum*, also called *S. esculentum*). It would take centuries for some Europeans to adopt tomatoes, but they found smoking tobacco more appealing after their first shock of seeing people "swallow smoke" (see *Nicotiana*).

Florida shares several species with neighboring areas, but three are prominent in the flora. Those with the most records of use by people are *S. bahamense*, *S. erianthum*, and *S. verbascifolium*.

*Solanum bahamense* is now called the Bahama nightshade in Florida, but that is surely a recent translation of the scientific name. More likely names actually used by the people are Bahamian canker berry, sometimes rendered kanky berry. "Canker" in those names seem to indicate a use in treating "thrush," especially of the mouth (von Reis and Lipp 1982). Thrush is an infection of the fungus *Candida*. Morton (1981) recorded that it was also called *ajicón* (big pepper), but did not indicate who uses that name. Mashed fruits are used to treat thrush, and to help children with nocturnal incontinence. Women also use the berries mashed in water as a drink to "check" to see if they are pregnant or have missed a menstrual period for some other reason (Morton 1981).

The Seminoles used two other species that are not that similar, but their names have been confused (Sturtevant 1955). Both have been incorrectly called *S. verbascifolium*. Now the most commonly used plants are known to be *S. erianthum*, and those formerly called *S. blodgettii* or *S. verbascifolium* are actually *S. donianum*. *Solanum donianum* is rarely used, even though the Seminoles call it *akkónónô:wî* (Mikasuki), or *akkononô:wâ* (Creek). Sturtevant (1955) considered the Mikasuki a simple term loaned from Creek. Wood from its stems were formerly used for arrows. Mullen nightshade [mullein nightshade] has been recorded as a common name for *S. donianum*, but that was probably an error for *S. erianthum*. Leaves on *S. erianthum* are woolly, much as they are in mullein (*Verbascum thapsus*, Scrophulariaceae).

*Solanum erianthum* is called *acolaki i:hici* (*vculyke*, old people, *em*, their, *hece*, tobacco, Creek) and *honaknô:sâ:lî imakcomî* (Mikasuki), with both names meaning "old people's tobacco." Others who compare it with tobacco call it *tabac marron* (wild tobacco, Hispaniola), tobacco tree, *tobaco bobo* (crazy tobacco), *tobaco cimarrón* (wild tobacco, Cuba), *tobaco del monte* (wild tobacco), *tabacón* (big tobacco), *tabacón afelpado* (hairy tobacco, Puerto Rico), *tabacón peludo* (hairy tobacco, Puerto Rico),

*tabaquillo* [*tobaquillo*, *tabacuelo*] (little tobacco, Dominican Republic), and wild tobacco (Puerto Rico). Apparently none of these people use the leaves as tobacco, but simply note the similarity. It is well that it is not smoked because it contains, among others, the alkaloids solanidine and solasodine (Morton 1981).

The names *amourette* (little love, Haiti), *zamorette* [*bâtard*] ([false] little love, Haiti), *zamorette male* (bad little love, Haiti), and *zamorette marron* (wild little love, Haiti) perhaps allude to the similarity to the tomato (*Lycopersicon esculentum*) that is sometimes called *pomme d'amour* (love apple). Mayan people also see that similarity, and say *tom-paap* [*toon-paap*] (*tom*, wild, *pak'*, tomato, Yucatan). The same relationship may include the Spanish name *galantea* (lover, Oaxaca). Other Spanish speakers sometimes say *guastomate* (*huaqui*, dry, *tomatl*, tomato, Náhuatl, Mexico).

Allusions to other members of the family Solanaceae are in the names *berengena* [*berenjena*] (eggplant, Veracruz), *berengena cimarrona* (wild eggplant, Puerto Rico), and *berengena de paloma* (dove's eggplant, Cuba, Puerto Rico). Some English-speaking people say it is the potato-tree, noting its similarity to *S. tuberosum*.

Several of the common names allude to some physical trait. Because the leaves have a foul odor when touched, *S. erianthum* has been called *hediondilla* (stinker), *pendejera hedionda* (stinking hanger, Cuba), and *pendejera macho* (male hanger, Cuba). Probably *zorillo* (little fox, skunk or opossum) makes the same reference because those are mammals with strong and unpleasant (at least to humans) body odors. To people in northwestern Mexico the flowers are *cornetón de monte* (wild horn, Sonora). The name *trompillo* (little funnel, Venezuela) also notes flower shape. *Hoja blanca* (white leaf) comments on the pubescent leaves. "Male *pito seco*" (Belize) is a mixture of English and Spanish meaning "male dry flower," unless it is a version of *malo pito seco* (evil dry flower). Also in Belize, they are *palo blanco* (white tree).

Several of the common names are untranslated and others make obtuse references. These include *allay muy* (Belize), *buey nini* (*buey*, ox in Spanish, Mayo), *lengua de buey* (ox tongue, Sonora), *mambia* (Mayo), *tai-mollaca*, *tapalayote* (maybe from *tapalacyoa*, referring to broken tile, but reference obscure, Náhuatl, El Salvador), and *xuhuy* (said to be Mayan, but no significance known, Yucatan). In Florida and Puerto Rico, the fruits are sometimes called turkey berry. That may be related to *zoza* [*sosa*] (tasteless, insipid, Morelos, Veracruz, San Luis Potosí, Sonora), and mean that the fruits are good only for turkeys. *Hoja de manteca* (butter leaf, Oaxaca) and *saca manteca* (butter maker, Sinaloa) are from using plant parts (which vary locally) to curdle milk.

Wild susumber looks like it should be a Creole variant of French *succomber*, and Latin *succumbere*, related to our English "succumb," or to overpower. "Susumber" is a reference either to medical uses or to similarity with *S. torvum*, a popular seasoning for foods (Grigson 1986). Either way, people throughout their ranges have utilized both species.

In Cuba and Mexico, the heated leaves of *S. erianthum* are used to relieve headaches by placing them on the forehead (Morton 1981). Similarly, leaves are poulticed on ulcers, boils, and burns (Standley 1920–1926, Martínez 1969). Venezuelans crush the leaves in oil to treat skin irritations, tumors, or swelling (Morton 1981). This use as a healing topical salve is reflected in big *saab* (*saab*=*salve*, Bahamas), *salvadora* (health giver, Tamaulipas), and *salve bush* (Bahamas). Leaf decoctions are used in Cuba as a

depurative drink (Roig 1945), while Mexicans use the liquid to reduce fever (Martínez 1969). Bahamians make a remedy of the leaves for colds and coughs (Eldridge 1975).

Medicinal application surely resulted in the name *gordo lobo* [*guardolobo*] (fat wolf, Nuevo León). Since the plants are such good remedies, they are also called *funga* (to supply, maybe from *fungir*, based on the old Latin *fungor*, Mexico), and *hierba de San Pedro* (St. Peter's herb, Nuevo León). Although no record of being laxative has been found in the Americas, the name *friega-plato* (plate breaker, Veracruz, Dominican Republic) suggests that usage. In Asia *S. erianthum* is used to treat dysentery (Hocking 1997).

Leaves and fruits are known to contain the alkaloids solaidine and solasodine (Morton 1981), among others (Zhou and Ding 2002). In spite of those potent compounds, they are considered only "slightly toxic" to cattle (Morton 1981).

My favorite names for these plants come from the Yucatan peninsula. There the plants are *yerba soler* (commonly used herb) in Spanish. That name succinctly condenses the many applications. The Mayas of Yucatan call them *xaxox* (*xux*, wasp, *ek*, star, or morning star). They do so because the flowers are open early in the morning and that is the same time that the wasps are most active. Many Mayan names are purely descriptive, but this one reveals their poetic soul.

### *Solidago*

(Latin for *solido*, to make firm, whole, or strengthen; decoctions were applied to cure wounds and ulcers)

*a'djidamo'wano* (squirrel tail, Ojibwa)

*amotci' hayi* (always dwells-in fields, Biloxi)

*chamizo blanco* (white sage, New Mexico, fide Cobos 1983, but Curtin 1947 applied this name to *Chrysothamnus*)

*eeche chatehche* [*itciçatistci*, *i:chicá:tíhcî*] (blind deer plant, Mikasuki); *éco-heceko* [*coheceko*, *cohicikô*] (*eco*, deer, *heceko*, blind, Creek, Muskogee)

flowers-of-gold

*fuinseag-coille* [*fuinnseag-coille*] (*fuinseag*, setting sun, *coille*, woods, Gaelic)

goldenrod (William Turner, in his herbal of 1568, wrote, "*Virga aurea*, may be called in English Golden-rod"); *Goldrute* (golden rod, German); *gullris* (golden rod, Norwegian); *vara de oiro* (golden rod, Portuguese); *vara de oro* (goldenrod, Spanish); *verge d'or* (golden rod, French,

*Solidago stricta* (narrow) (fide Sturtevant 1955)  
willow-leaf goldenrod

*Solidago ulmifolia* (elm-leaved)  
elm-leaved golden-rod

Linnaeus used a number of methods to gain the interest of his students, among them planting a “floral calendar” at his home. He was not the first to use plants as indicators of the seasons; non-industrial people had been doing that for thousands of years. Gilmore (1919) recorded that application among the Omaha of the Missouri River region. These people considered *Solidago* a part of the natural almanac. He wrote: “Goldenrod served the Omaha as a mark or sign in their floral calendar. They said that its time of blooming was synchronous with the ripening of the corn; so when they were on the summer buffalo hunts on the Platte River or the Republican River, far from their homes and fields, the sight of the goldenrod as it began to bloom caused them to say, ‘Now our corn is beginning to ripen at home.’”

Before exploration of the New World began, Europeans knew a single species of goldenrod, *S. virgaurea*. That herb had been considered medicinal from the time of the classical Romans, probably earlier. Linnaeus ([1753] 1957) adopted the old Latin name for the species, *virga aurea* (goldenrod). Known in the pharmaceutical trade as *Radix et Herba Virgae aurea*, *Herba [Solidaginis] Virgaureae*, or *Herba Consolidae Saraceniae*, the species was considered carminative, diuretic, nervine, extitant, and digestive (Uphof 1968, Hocking 1997).

By the 16th century, the Old and New World species were famous for their medical properties. Typical of the time are the comments by John Gerarde ([1597] 1975) who wrote of the goldenrod: “It is extolled above all other herbes for the stopping of blood in sanguinolent ulcers and bleeding wounds; and hath in times past beene had in greater estimation and regard than in these dayes: for in my remembrance I have knowne the dry herbe which came from beyond the sea sold in Bucklers Bury in London for halfe a crowne an ounce. But since it was found in Hampstead wood, even as it were at our townes end, no man will give halfe a crowne for an hundred weight of it; which plainly setteth forth our inconstancie and sudden mutabilitie, esteeming no longer of any thing, how pretious soever it be, than while it is strange and rare. This verifieth our English proverbe, Far fetcht and deare bought is best for ladies.” He should have said “people.”

Since Linnaeus ([1753] 1957) wrote about these plants, more species have been found. *Solidago* is now a genus of about 80 species with a few species in South America, Macaronesia, and Eurasia (Mabberley 1997, Diggs et al. 1999). Formerly there were more species in *Solidago* (see Fernald 1950, Steyermark 1963), but many have been moved to other genera.

Moerman (1998) listed 19 species used across North America by many tribes. Throughout the world, many other species have been used by different cultures (Gerarde [1597] 1975, Culpeper 1653, Uphof 1968, Hocking 1997, Mors et al. 2000).

The genus was formerly a well-known dye plant, flowers producing a yellow-green (Tull 1999). Seminoles still use the flowers and stems as the source of a dye (Bennett 1997). Porcher (1863) also recorded that *S. canadensis* was “[u]sed in Canada as a most

valuable dye. ...The leaves and flowers of the English species are used for making a yellow dye; said to be as good as woad [*Isatis tinctoria*].”

Porcher (1863) listed, “Among our native substitutes for hemp... *Solidago canadensis*... Its stalks are numerous, straight, and grow almost five feet in height; they afford very strong fibres if treated in the same manner as hemp.” The Keres also used *S. gigantea* to weave rough baskets (Moerman 1998).

Among the Florida species used by different people are *S. canadensis*, *S. gigantea*, *S. nemoralis*, *S. odora*, *S. rugosa*, *S. sempervirens* var. *mexicana*, and *S. ulmifolia*. Several reports are simply listed under the genus, and more species may have been employed.

The Iroquois used *Solidago canadensis* to treat side pains, as an emetic, to “kill” or counteract a love potion, as a “gambling medicine,” and as a medicine to treat babies who awaken suddenly. The Meskwaki used Canada golden-rod in a wash for a child who does not talk or laugh. The Ojibwa applied it to burns, boils, and ulcers. The Potawatomi treated some fevers with it (Smith 1933). The species was also medicinal among the Okanagan-Coville, Shuswap, Thompson, Zuni, and the New Mexican Hispanics (Curtin 1947).

Subsequently, *S. canadensis* has been considered a carminative, diuretic, and stimulant in herbal stores (Hocking 1997). It is the source of Canadian goldenrod oil. Duke et al. (2002) retain the Latin name but note that the material available in the markets might come from any of a number of species. They list the plants as having been used against cancer, inflammation, spasms, and as both diuretic and emetic.

Although Uphof (1968) considered *S. canadensis* an emergency plant food, it was not listed as edible by Fernald et al. (1958). Still, *S. canadensis* and *S. nemoralis* were eaten by the Gosiute and Navajo (Yanovsky 1936), and Foster and Duke (1990) note that *S. canadensis* seeds were eaten as survival food.

*Solidago gigantea* was used by the Keres as a strong physic. The Menomini, Ojibwa, and Potawatomi treated fever with a flower decoction (Densmore 1928, Smith 1933, King 1984, Moerman 1998). Hocking (1997) noted that this species had been used as a gargle tea in treating pharyngitis, tonsillitis, and stomach problems.

*Solidago nemoralis* was used by the Houma to treat jaundice (Speck 1941). The Iroquois treat kidneys with a decoction of the roots (Moerman 1998). The Navajo still use it for incense (Moerman 1998). Hocking (1997) recorded that the species was used in domestic medicines.

Perhaps the most famous use of *S. odora* is as a tea substitute. This tea was especially popular during the Revolutionary War. Fernald et al. (1958) thought that Johann D.Schoepf, who was the chief surgeon of one of the bodies of German troops sent to America by George II during the Revolution, was one of the first to record this beverage. While visiting North America in 1783–1784, Schopf wrote from Bedford County, Pennsylvania: “Here we were introduced to still another domestic tea-plant, a variety of *Solidago*. The leaves were gathered and dried over a slow fire. It was said that around Fort Littleton many 100 pounds of this Bohea-tea, as they call it, had been made as long as the Chinese was scarcer. Our hostess praised its good taste, but this was not conspicuous in what she brewed.”

When the Americans rebelled against British taxes by dumping a cargo of taxable tea into Boston Harbor, they decided to use a native substitute. This “Liberty Tea,” as they called it, was made from the same leaves that Schopf decried. Not everyone was as

negative about the tea from *S. odora*, and Frederick Pursh wrote in 1807, “The flowers, gathered when fully expanded, and carefully dried, give a most agreeable substitute for tea, which for some time has been an article of exportation to China, where it fetches a high price.”

Rafinesque (1828–1830) also regarded the tea as highly as Pursh. He wrote: “This [species is] easily known by its sweet scent near to aniseed. Essential oil of it has the same sweet scent, much used for head ache, in frictions. Whole plant aromatic, stimulant, diaphoretic, carminative, useful in flatulence, nausea, spasms of the stomach; chiefly used as a grateful tea. Leaves prepared like tea have been sent to China, much used in some parts of our country, used in fevers by Cherokees.”

During the Civil War, Porcher (1863) encouraged people in the South to use this drink. He wrote, “According to Pursh, the dried flowers are a pleasant and wholesome substitute for tea.”

Later people describing the tea from *S. odora* thought that the air-dried leaves had an odor like licorice, and said that they were used to make “goldenrod tea” (Correll and Johnston 1970). Hocking (1997) thought that it had the odor of fennel or anise. He also considered it carminative, stimulant, and diaphoretic when used to make a beverage tea (as Blue Mountain tea), with a flavor similar to catnip tea.

There were also medical uses of *S. odora*. Because the plant played such an important part in the Revolutionary War and served as an export to China, it seems odd that only one tribe is known to have used it. The Cherokee treated colds, coughs, diarrhea, female problems, fevers, nerves, sore mouth, and tuberculosis with these plants as a diaphoretic, stimulant, and tonic (Hamel and Chiltoskey 1975).

Jacob Bigelow wrote in his *American Medical Flora* of 1817–1820: “The claims of the *Solidago* to stand as an article of the Materia Medica are of an humble, but not despicable kind. We import and consume many foreign drugs which possess no virtue beyond that of being aromatic, pleasant to taste, gently stimulant, diaphoretic and carminative. All these properties the Golden Rod seems to fully possess.”

Porcher (1863) wrote of *S. odora*: “An aromatic, moderately stimulant, and carminative plant, and like other substances of the same class, diaphoretic in warm infusion. It is used to allay pain from flatulence, lessen nausea, and cover the taste or correct the operation of irritating or unpleasant medicines. Mérat states that the infusion is also employed as an astringent in dysentery, and in ulceration of the intestines. ...When the leaves are subjected to distillation a very aromatic, volatile oil collects, and an essence may be made by dissolving this in proof spirits. This will also stop vomiting and correct the taste of medicines, even laudanum and castor oil;...it is valuable in allaying the pain from headache, externally applied. It is much used in the Eastern states, and Bigelow thinks it will entirely supplant more expensive articles.”

*Solidago rugosa* is recorded as being used only among the Iroquois. This alliance of tribes treated liver disease, weakness, dizziness, and sunstroke with the species (Moerman 1998). Hocking (1997) recorded that it was used to treat fever by Mississippi blacks.

*Solidago sempervirens* has been used to treat wounds and warts (Hocking 1997). No records have been found of it being used by indigenous tribes other than the Seminoles. Porcher (1863) considered the species, “[v]ery efficacious in the cure of wounds.”

*Solidago ulmifolia* is known to have been used by only two tribes. The Meskwaki and Ojibwa used smoke from the burning herb to revive unconscious persons (Densmore 1928, Vogel 1970, Hocking 1997).

There are records of several other tribes using *Solidago*. No species identifications were made, and they may have been other species, or they might be those listed above. The Alabama used some species to treat colds and toothaches (Swanton 1928a, Taylor 1940). The Algonquin treated heart disease; the Blackfoot chewed roots for sore throat and nasal congestion (Moerman 1998); the Cherokee used it to treat fever; the Iroquois used it to stop internal bleeding; and the Ojibwa applied roots externally to stop cramps (Moerman 1998).

Swanton (1928) found the Creek using *Solidago*, as did their relatives the Alabamas, Houmas, and Miccosukees. Miccosukees called the plant “blind deer plant,” but Sturtevant’s (1955) informant considered it useless. That lapse of information is typical of the spotty knowledge of individuals, because Alice Snow now uses goldenrod, applying the same name, as an ingredient for cough medicine (Snow and Stans 2001). In addition, other individuals gave information to Bennett (1997).

Medical use of *S. virgaurea* is founded on saponins, which are antifungal, and rutin and phenolic glycosides, which are anti-inflammatory (Bown 1995).

*Solidago odora* was the only species to be listed in the U.S. Pharmacopoeia, from 1820 to 1882. Its properties were defined as stimulant, carminative, and diaphoretic (Vogel 1970).

In addition to the chemicals known from the European species, the American plants contain a variety of compounds. Golden-rod oil (volatile oils with pinenes, limonene) has been extracted from *S. canadensis*, *S. gigantea*, *S. nemoralis*, *S. odora*, and *S. rugosa* (Uphof 1968). Sometimes, that from *S. canadensis* is distinguished as “Canadian Golden-rod oil.” Perhaps it has a distinct name because the volatile oils in *S. canadensis* also contain cyclocolorone, carophyllene, borneol, cadinene, and terpene hydrocarbons (pinene, phellandrene, diapentene) (Hocking 1997). The others vary somewhat: *S. nemoralis* has pinenes and phenols; *S. odora* has estragol, borneol, bornyl acetate, and limonene; and *S. rugosa* contains pinenes and limonene.

*Solidago canadensis* also contains quercetin and rutin; *S. gigantea* has saponins; and *S. sempervirens* has dihydromatricaria ester in the roots (Hocking 1997). Inventor Thomas A. Edison found that *S. sempervirens* produced caoutchouc, and for some years he explored it as an alternate rubber (Hocking 1997). There has recently been a renewed interest in *Solidago* as an alternate rubber source (Anonymous 1990a, b, Tanaka et al. 1995).

### *Sophora*

(Linnaeus took the Arabic name *sophera* or *safayra*, yellow, and applied it to *S. alopecuroides*)

#### *Sophora tomentosa* (woolly)

coast [yellow] sophora (book names, Bahamas, Texas)

*haricot bâtard* (false kidney bean, Guadeloupe, Martinique)

micar (Cayman Islands)  
necklace pod (Florida)  
sea-coast laburnum (Australia)  
silver-bush (USA)  
*tambalista* [*tambalisa*] (Cuba)

*Sophora tomentosa*. Drawn by  
*P.N.Honychurch*.

Linnaeus coined *Sophora* in 1738 and formalized it in 1753. There are now 45 species in the genus, which is known from both tropical and temperate regions. Europe has 2 species, and there are 9 in North America (Kartesz 1994). Vestal and Schultes (1939) and then Merrill (1977) made the southwestern North American species *S. secundiflora* one of the most famous in the genus because of its use among the Kiowa.

Reputed to be diuretic, sudorific, and purgative, *Sophora* has been used in the West Indies against venereal disease (Standley 1920–1926). In the East Indies, the root bark and seeds were used as a remedy for cholera, diarrhea, and the consequences of food poisoning, especially ciguatera (Burkill 1966). Powdered seeds were used by Malays against diarrhea, and both roots and seeds were used to treat external wounds and other skin problems (Burkill 1966). People in the Philippines use the herbage and seeds as a remedy for stomach ailments, and in New South Wales in bilious sickness (Uphoff 1968).

Seeds are poisonous; they contain cytisine and related alkaloids with properties similar to nicotine (Cribb and Cribb 1981, Lampe and McCann 1985). All parts of plants contain poisonous alkaloids (Standley 1920–1926). The juice of the plant has been used as a fish poison in east Africa and as an insecticide in Fiji (Hocking 1997). Presumably, this species contains sophorine; it may have been used in the Americas as an intoxicant as was *S. secundiflora* (Merrill 1977). Beans of *S. tomentosa* are used in China for intoxication (Hocking 1997).

*Sparganium*

(Greek name used for the European species by Pliny, A.D. 23–79, and Dioscorides, fl. A.D. 40–80, from *sparganion*; derived from *sparganon*, a swaddling band, an allusion to the ribbon-like leaves)

bur-reed (“bur” or “burr” is of uncertain etymology, but it alludes to a rough flower head or seed head; cognate with Danish *bone*, bur, and Swedish *borre*, sea-urchin; John Gerarde wrote in 1597, “These plants of some are called Sparganium... I rather call them Burre Reede”)

*Igelkolben* (hedgehog bloom, German)

*piggknopp* (spike bud, Norwegian)

*sala* (literally “twill,” but plant material used “to stuff with straw” or “to cane a chair,” Italian)

*seisg madaidh* (*seisg*, sedge, *madaidh*, dog, Gaelic)

*Sparganium americanum* (of America)

[American, three-square] bur-reed [burreed]

*ho'-xthon ta-xe* (Osage; a sacred plant used in ceremonial rites)

*rubanier* (ribbon plant, Quebec)

Dioscorides used two related words in markedly different contexts. One of the words was *sparganion*, from which Linnaeus derived the generic name

***Sparganium americanum*.** From  
Institute of Food and Agricultural  
Sciences.

*Sparganium*. Botanical sources say that Dioscorides and Linnaeus based the name on the ribbon-like leaves of these wetland plants (e.g., Fernald 1950, Munz 1973, Quattrocchi 1999). However, Dioscorides also wrote about *sparganosis* or *spargosis*. Those two words are based on Greek *spargar*, to swell, and refer to breasts swollen with milk (OED 1971). Could it be that both Dioscorides and Linnaeus were talking about the swollen fruit clusters in the plants? At least since the time of Gerarde, these cattail relatives have been called “bur-reed,” in reference to those enlarged fruits. That duality of meaning is just the kind of complexity that Linnaeus loved to use in names.

*Sparganium* grows from the Mediterranean through most of Europe, and the species that Dioscorides knew still has the name he gave it. Linnaeus knew only two European species. Today there are 14 in the genus worldwide, with 7 in Europe and 10 in North America (Mabberley 1997). Biologists have long thought that reed-maces (cattails) and bur-reeds were closely related. Although Wunderlin (1998) continued using distinct families for them, others combine them into the single family, Typhaceae (Judd et al. 2002).

Indigenous people knew bur-reed as a source of food, although considerable energy had to be expended for a comparatively small return. The creeping roots bear tubers that have been gathered and eaten, although actual records have been found for only the Klamath of Oregon eating them (Fernald et al. 1958, Moerman 1998). While cattails are famous for their edible young staminate inflorescences, Judd et al. (2002) indicate that *Sparganium* may be similarly eaten. A practice related to food, but not actually eating these plants, is recorded for the OkanaganCoville who lined cooking pits with the leaves (Moerman 1998).

In the East, only the Iroquois are known to have used bur-reed in medicine. They made an infusion that was drunk to relieve chills, and put the herbs into a more complex mixture for another purpose. The Iroquois believed that it was possible to cast a spell on another individual, and one symptom of the enchantment was that men were “sore all over.” The complex herbal mixture was used to counteract that magic (Moerman 1998).

A side benefit to *Sparganium* that indigenous people surely utilized is that the fruits are a favored food for wildlife. As Martin et al. (1951) wrote, “They are more plentiful in the North, and it is here that they have their principal importance for wildlife.” Their book *American Wildlife & Plants* listed 19 different species of waterfowl, marsh, and shorebirds that ate the seeds. Among those are many that were favored food for indigenous people such as 11 species of ducks, cranes, and snipe. Muskrats (*Ondatra zibethicus*), another animal favored by many tribes, “use the whole plant” (Martin et al. 1951). In Florida, that species is replaced by the round-tailed muskrat (*Neofiber alleni*), and it too may have favored the plants.

### *Spartina*

(Johann Christian Daniel von Schreber, 1739–1810, named the genus with Greek *spartine*, *sparton*, a rope; akin to Latin *spartum*, a grass used for cordage, nets, and mats, Akkadian *sabaru* and Hebrew *safar*, to bind)

cord grass (USA, England)  
 marsh-grass (USA); *marskgras* (marsh-grass, Norwegian)  
*Reisgras* (rice grass, German)  
*Schlickgras* (slime grass, German)  
*spartine* (French)

***Spartina alterniflora*** (alternate leaved)  
 [salt-marsh, saltmarsh, saltwater, smooth] cordgrass [cordgrass]  
 (Florida, northeastern USA, Texas)  
*herbe salée* (salt grass, Quebec)

***Spartina bakeri*** (named for C.H.Baker, who collected the type specimen in Florida on 19 April 1898)  
 sand cord-grass [sand cordgrass] (Florida)

***Spartina patens*** (spreading or diverging, from the spikes bending out from the axis)

[marshhay, salt-marsh, salt-meadow, saltmeadow] cord-grass [cordgrass] (east coast USA to Texas, Bahamas)

highwater grass (northeastern USA)

*musotte* (not French; perhaps an indigenous word, Quebec)

salt grass (Puerto Rico)

*yerba de sal* (salt grass, Puerto Rico)

***Spartina spartinae*** (a cord)

Gulf cord-grass [Gulf cordgrass] (Florida, Texas, Bahamas)

*sacahuista* (*zacatl*, grass, *cuahuatl*, tree, Náhuatl, Texas)

Jonathan Dickinson's was one of the few historical documents commenting on the houses built by the Glades people (Andrews and Andrews 1945). He mentioned thatch only with palm leaves. The earlier account by Cabeza de Vaca, speaking of the people on the Gulf Coast, said, "Their huts were of mats erected on piles of oyster shells" (Cabeza de Vaca in Gilliland 1975). Mats could have been made of a number of plants. However, the Marco Island archaeological site provided more evidence of housing materials. Gilliland (1975) quoted from archaeologist John M. Goggin's manuscript that "these [houses] consisted of palmetto and marsh grass thatch." Unhappily, none of the fibers recovered was preserved well enough for Gilliland to make a positive identification.

However, Goggin's comments, and the record of other people using *Spartina* in thatching is compelling. Gilmore (1919) records that the people of the Missouri River region used slough grass (*S. pectinata*) to thatch their earth lodges. The Omaha-Ponca called it *sidu-hi*. The Iroquois are documented as using *S. alterniflora* in a different way, as "forage," presumably for livestock (Moerman 1998).

## ***Spigelia***

(With this name, Linnaeus commemorated the Dutch physician Adriaan van der Spiegel, 1578–1625, professor of anatomy and surgery in Padua)

***Spigelia anthelmia*** (against worms)

*arapabaca* (cow killer, Minas Gerais, Brazil)

*Brinvillière* [*Brinvilliers*, *herbe-Brinvilliers*] (Guadeloupe, Martinique)

*caricia* (dear one, Colombia)

*cuntv-heleswv* (*cuntv*, worm, *heleswv*, medicine, Muskogee)

*dronkegoeman* [*droengoeman*, *droegoman*] (drugman, Sranan, Suriname)

*espigelia* (Hispaniola)

*guambiá* (child's luck, Colombia)

*herb-poison* (poison herb, Guadeloupe, Martinique)

*inanusu* (Cuna)

*kinchan* (Zoque-Popoluca, Veracruz)

*koroka* (Carib, Suriname)

loggerhead-weed [loggerhead weed] (Barbados)

*lombricera* [*lombricero*] (wormer, Puerto Rico, Mexico, Panama, Colombia, Venezuela); *lombricera del pas to* (worm grass, Puerto Rico); *lombrigueiro* (wormer, Minas Gerais, Brazil), *pega pinto* (symptom stopper, Peru); worm grass [bush] (Jamaica, Virgin Islands, Nicaragua, Panama); *yerba [hierba] lombricera* (worm herb, Cuba); *yerba de lombrices* (worm herb, Dominican Republic); *zacate de lombriz* (worm grass, Nicaragua)

pink (Bahamas); pink weed (Jamaica); West Indian pinkroot (Florida)

*poudre a vers* [*poudre aux vers*] (powerful powder, Haiti, Guadeloupe, Martinique)

*quiteria* (expeller, Colombia)

*tebeyuballi* (*tebeyu*, a name for five other genera, *balli*, resembling, Arawak, Suriname)

water grass (this name and the following apparently allude to watery stools, Virgin Islands); water weed (Barbados)

***Spigelia marilandica*** (of Maryland)

*ala imokhinsh* (*ala*, arrival, *im*, its, *ikhinsh*, medicine, Choctaw; used as a “tonic”); perhaps this is *chokfisholosh* (*chokfi*, rabbit, *im*, its, *sholosh*, shoe, Chickasaw)

*mi-ka-k'e* [*mekaa*, *mikaa*] (Osage; literally, “star”; called “starflower” by Hunter [1823] 1973; Millspaugh 1892 does not give his source for identifying the plants as *Spigelia*, but it was probably from Rafinesque’s *Medical Flora* of

Marggraf brought the Europeans’ attention to these medicinal plants in early 1648. He called one species *Arapabaca brasiliensis dicta planta* (the plant Brazilians call *arapabaca*). Charles Plumier also used the Brazilian name in 1703. Linnaeus did not believe in other people using “foreign” (i.e., non-European) names for genera, and coined the genus with *Spigelia anthelmia*. There are now 50 species in the tropical and warm parts of the Americas (Mabberley 1997).

Vogel (1970) thought that the North American species *S. marilandica* became known in Europe when physician Alexander Garden of Charleston learned of its use from the Cherokee. By 1752, Garden had sent specimens to European colleagues, and in 1768 he sent a specimen of it to physician Cadwallader Golden with the comment that it was “an Excellent anthelmintic Given either in powder or Decoction” (Vogel 1970). In spite of Vogel’s (1970) version of medical use, the actual European history is considerably older.

*Spigelia marilandica* was first collected by Hugh Jones in Maryland. After arriving in 1696 as a chaplain, Jones did not live up to the expectations of Royal Governor Francis Nicholson, and he was assigned to the Christ Church Parish in Calvert County where he spent much of his time collecting plants (Reveal 1992a).

***Spigelia*.** *Spigelia anthelmia* (right), a. Habit, b. Papillae on surface of leaves, greatly enlarged, c. Flower bud, d. Flower, side view, e. Flower, longitudinally dissected, f. Floral diagram, g. Fruit, h. Seed. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982. *Spigelia marylandica* (left). From Britton and Brown 1897.

1828–1839); starbloom; starflower (from Hunter [1823] 1973)  
 [Carolina, Indian]-pink  
 [woodland] pinkroot (in use since at least the 1720s when Catesby was in South Carolina; the first record found by OED 1971 was 1763 in a record of the *Produce of South Carolina*—one cask was listed for export)  
 snakeroot  
*unsteetla* [*unstill*] (Cherokee)  
 wormroot

John Ray in 1704 was one of the first to mention these American herbs in his *Historia plantarum*. He called them *Perichlymeni virginiani flore coccinea planta marilandica* (Virginia honeysuckle with a red flower, plants from Maryland). Probably Ray's examples were cultivated and no herbarium samples made. Important specimens in Europe were sent there from Charleston by John Clayton in the 1730s. Jan Gronovius used the Clayton specimen, now preserved in the British Museum of Natural History in

London. In his *Flora Virginica* of 1739–1743, Gronovius called the plants *Lonicera spicis terminalibus, foliis ovato-oblongis acu-minatis distinctis sessilibus* (Honeysuckle with terminal spikes, and distinctly sessile ovate-oblong and acuminate leaves). Gronovius knew about the medical uses of the plants because he cited Catesby (1734). Catesby had ample opportunity to learn about them because he was in Williamsburg, Virginia, between 1712 and 1719. He returned to England, then went back to Charleston, South Carolina, in May of 1722. Somewhere between 1712 and his return to England in 1726 to publish his book, he learned about the vermifuge properties of “pinkroot” and wrote, “A Decoction made of this Plant is good against Worms” (Catesby 1734). Physician Benjamin Rush, in 1774, considered *S. marylandica* and *S. anthelmia* to be “two of the most powerful vermifuge medicines we are acquainted with.”

The Cherokee, Choctaw, Creek, and Osage used *S. marilandica* to expel worms (Hunter [1823] 1973, Swanton 1931, Taylor 1940, King 1984, Moerman 1998), and others within its range (Maryland to Oklahoma and south to Texas and Florida) probably also did. Vogel (1970) wrote that, among settlers, “For almost two centuries this [*S. marilandica*] was the most celebrated vermifuge on the American continent.”

From the earliest reports, the Creeks considered *S. anthelmia* a “well-known” remedy for expelling worms in children (Swanton 1928a). Since the herb has always been confined to what the Seminoles called *ekan-yuksa* (point of land) of southern Florida (Miami-Dade and Monroe Counties), they either learned about it from their predecessors, or through extrapolation from formerly having used the more widespread *S. marilandica*.

In the Caribbean and elsewhere within the range of *S. anthelmia*, most people have used the herb to expel intestinal worms. Roig (1945) found it being used in Cuba, and common names and records show use in the other islands (Petersen 1974, Proctor 1984). People from the Chocó and Cuna of Panama to French Guiana and Brazil also use *S. anthelmia* to eliminate parasites (Duke and Vásquez 1994, Mors et al. 2000).

In the Caymans, people know that cut and wilted pink weed “is extremely dangerous and may cause fatalities among livestock; the fresh plant is apparently less dangerous” (Proctor 1984). Small doses are effective vermifuges, but large doses can kill (Duke and Vásquez 1994). Caribbean people know that pink weed has been used in criminal poisonings (Uphof 1968). The plants contain isoquinoline and one iridoid, both of which are cardiotonically active (Wagner et al. 1986).

Other uses include the leaves to repel cockroaches and flies. In light doses it is effective against stomach-aches; Chocó use it as laxative (Duke 1972). In addition, a root infusion is used to bathe children as a sedative and tranquilizer in northwestern Amazonia (Schultes and Raffof 1990).

### *Spiranthes*

(Named from Greek *speira*, a spiral or coil, and *anthos*, flowers, in reference to the spiral or twist of the inflorescence)

*Spiranthes*. a to g. *Spiranthes ovalis*; a. Habit of plant, b. Flower, side view. c. Lip, side view. d. Lip, spread out. e to g. Variation in leaf tip venation and shape, h to j. *Spiranthes cernua*; h. Habit of plant, i. Flower, side view, j. Lip, spread out. k. *Spiranthes odorata* with lip spread out. Drawn by Gordon W.Dillon. From Correll and Correll 1972.

bayonet-lily (Newfoundland)

*Drehwurz* (twisted herb, German)

*ibis* (allusion obscure, *ibis* the Greek and Latin name for a wading bird; for *S. torta*, Puerto Rico)

ladies'-dresses (a corruption or variation on either "ladies'-tresses" or ladies'-traces")

ladies'-traces (comparing the flower cluster to a braid; a name that has been used since at least the time of Turner's *Names of Herbes* of 1548, when he wrote, "Satyrion...bryngeth furth whyte floures in the ende of harueste, and it is called Lady Traces"; Dodoens wrote in 1554, "The sweete Orchids, or Ladie Traces are moste commonly to be found in high, untilled, and dry places"; some spelling variant of ladies'-traces was used at least until 1794)

ladies'-tresses [lady's-tresses, ladiestresses orchid] (a spelling given to these orchids since 1842 when used in C.W.Johnson's *Farmer's Encyclopedia*; the name compares them to women's braided hair)

orphrys (from Middle English *orfreis*, ultimately from Latin *auriphrygium*, Phrygian or goldembroidered garments; akin to Old French *orefris*, Portuguese *aurfres*; name for *S. tortilis* used by Williams [1837] 1962)

pearl-twist

*Satyrion à trois couillons* (literally, "Satyr with three testicles," but translated by John Cotgraves as "triple orchis, or Ladies traces" in his 1611 book *A Dictionary of the French and English Tongues*); *testicolo odoroso* (fragrant testicle, Italian)

*skrueaks* (*skru*, screw, Norwegian); spiral-orchid (New Hampshire, Texas); *spiranthe* (French)

*Wendelhäre* (spiral-hair, German)

These terrestrial orchids have been known as "ladies'-traces" or "ladies'-tresses" since at least the 1540s when they were listed by British herbalist William Turner. Indeed, Linnaeus knew some of them in 1753, but he included them within his genus *Ophrys* (eyebrow, because of hairy flower labellum or lip). It was not until after Louis Claude Marie Richard (1754–1821) had studied plants in South America and the Caribbean that the genus *Spiranthes* was created for them in 1817.

Europe has three or perhaps four *Spiranthes*, and most of the others are in the northern temperate zones (Mabberley 1997). Liogier and Martorell (1982) included eight species in Puerto Rico, although at least four of those are now placed in other genera. Kartesz (1994) recognized 35 species and a named hybrid in North America and Greenland, although Mabberley (1997) said there were only 30 species in the genus. Those differences are typical of individual interpretations of the genus.

As other names like *Satyrion* (the Greek *satyr*, who was lascivious), *Orchis* (testicle, Greek), orchid (testicle), and even the family name Orchidaceae, suggest, there has long been an association of these monocots and sexuality. Those names came into existence because some of the plants bear two rounded bulbs at their base with an uncanny resemblance to human anatomy. The beliefs in Europe may be illustrated by one example. In 1597, John Gerarde wrote of *Spiranthes*, "The full and sappy roots of Ladie traces eaten, or boyled in milke and drunke, provoke venery, nourish and strengthen the bodye, and be good for such as are fallen into a consumption and Fever Hectique." Many more examples exist for *Orchis* and others (e.g., Bedigian 2001, Gibson 2001).

Apparently, that same notion existed among indigenous Americans. The Gosiute, for example, used *S. romanzoffiana* against venereal disease (Moerman 1998). The same

ideas may have been inherent in the Cherokee use of an *S. lucida* infusion as a wash for infants to ensure fast healthy growth, and mixing it with roots of tway-blade (*Liparis lilifolia*) for urinary trouble (Hamel and Chiltoskey 1975). At least, the power they believed resided in the plants is clear from the Ojibwa use of roots of *S. lacera* var. *gracilis* as an ingredient of the hunting charm to bring game to the hunter (Moerman 1998).

The only record found of Florida tribes using *Spiranthes* was made by Small (1933). Under the heading of the Ladies'-tresses he wrote, "A decoction made from the roots of some of the species is used by the Seminoles as a blood purifier." That may be a valid medical use, as other members of the genus are known to be medically active. For example, *S. diuretica* has been used to treat the urinary system (Lewis and Elvin-Lewis 1977).

While Gerarde recorded that Europeans ate orchid roots, and other genera are notably edible (Bedigan 2001, Gibson 2001), there is a single record of indigenous tribes eating *Spiranthes*. The Paiute ate roots of an unidentified *Spiranthes* (Moerman 1998).

Luer (1972) thought that the common name ladies'-traces came from "the traces or strings of a woman's bodice." Actually, the application is older than that women's clothing style. The word "trace" and its plural "traces" have meant a braid or plait of hair since at least A.D. 1380. By 1539, it was broadened to mean a braid of gold or silver used to trim the border of a robe, and by 1678, a string of maize (*Zea mays*) ears plaited together by the husks (OED 1971).

However, the word "tress" is just as old. It too appears in English in the 1300s. Chaucer himself wrote in 1386 about a woman that "Hir yelow heer was broyded in a tresse Bihynde hir bak, a yerde longe I gesse." Both "tress" and "trace" are cognates with French *tresse*, which came from Old French *tresce* (used in the 12th century for a braid of hair). Those words are also related to *tressa* or *treza* (Portuguese) and *treccia* (Italian). There are also infinitives *tresser* (French), *trecier* (Old French), and *tree ciare* (Italian). The derivation of these words in all these languages may be from Greek *tricha*, "threefold, or a triple plait."

### *Sporobolus*

(From Greek *spora*, seed, *bolos*, casting; the scientific and common name "dropseed" both refer to the seeds being dispersed)

*Sporobolus virginicus*. Drawn by Edna May Whitehorn. From Hitchcock and Chase 1950.

***Sporobolus pyramidatus*** (pyramid-shaped, alluding to the inflorescence)  
*brak grass* [*brakgrass*] (break grass, Dutch Antilles); *brakgras doeshi* [*bragaadushi*] (sweet break grass, Dutch Antilles)  
*chiendent* (dog tooth, Haiti)  
 match grass (Bahamas)  
 whorled dropseed (Bahamas, USA)  
*yerba fini* (fine or slender herb, Dutch Antilles)

***Sporobolus virginicus*** (from Virginia)  
*chiendent* [*chien dient*] (dog tooth, Haiti)  
 crab grass (Barbados)  
 [seashore, coastal] dropseed (“dropseed” was first used for a *Muhlenbergia* in 1866 and Robert Brown created *Sporobolus* in 1810, northeastern USA, Carolinas, Florida, Texas, Bahamas)  
*grama* (grass, Spanish)  
*herb* [*zeb*] *bord de mer* [*lan-mer*] (seaside herb, Guadeloupe, Martinique)  
*matojo de burro* [*de play a*] (donkey [beach] thicket, Puerto Rico)  
 [sea-shore] rush-grass [seashore rush grass] (north-eastern USA, Bahamas, Puerto Rico)  
*saladilla* (little salty one, Venezuela); salt grass (Florida)

Robert Brown described *Sporobolus*, based on grasses from India. Much earlier, John Clayton had sent Linnaeus grasses from Virginia, and among them was one that he called *Agrostis virginicus*. Lamarck made the same choice of genus in 1791 when he named *Agrostis pyramidatus*. Both were moved to *Sporobolus* much later, and other species added to them brought the total to 160, with different kinds growing in Africa, the Americas, and Asia (Mabberley 1997).

In the Caicos Islands, dry *S. pyramidatus* is used for kindling; it ignites quickly and makes a hot fire (Morton 1981). A decoction of the grass is diuretic. The mixture is used to treat severe fever and colds, as a purge in Curaçao, and as a laxative in Aruba (Morton 1981).

In Coró, Venezuela, decoctions of *S. virginicus* are taken to cure urinary irritation and kidney complaints. The grass is also made into a gargle (Morton 1981, Hocking 1997).

### *Stachys*

(From Greek *stachys*, ear of wheat or spike, because of the terminal spike or raceme)

*ande'gobüg* (crow foot, for *S. palustris*, Ojibwa)

betony (from Latin *betonica*, which Pliny, A.D. 23–79, said was a Gaulish name from *vettonica*, derived from Vettones, people of Lusitania, *S. officinalis*); *betoine* (Dutch, Norwegian); *bétoine* (in use by 1550, French); *betonica* (in use by 1551, Italian); *betonica* (in use by 1557, Spanish); *Betonik* (in use by 1542, German)

*brisgean nam caorach* (brittle one of the sheep, for *S. palustris*, Gaelic)  
*épaire* (from *epi*, spike, because of the form of the inflorescence, Quebec)

hedge nettle (an allusion to where the plants grew and the similarity of their leaves to nettle or *Urtica*; in use by 1678)

*kestron* [*cestron*] (Greek for a graving tool or hammer, for *S. officinalis*, used by Dioscorides, fl. A.D. 40–80)

*lus nam sgor* (plant of the sharp rocks, for *S. sylvatica*, Gaelic)

*ortiga hedionda* (stinking nettle, for *S. officinalis*, Spanish)

*psychotrophon* (*psycho*, cold, *trophon*, turning, because it grows in cold dark places, for *S. officinalis*, Greek)

*svinerot* (*svine*, hog, *rot*, root, Norwegian)

woundwort (dating from at least 1548 when Turner wrote in his book *Names of Herbes*, “woundewurte,” but he applied it to *Solidago*; John Gerarde perhaps used it for *Stachys* in 1597, but he also used the name for *Solidago*; the name was applied to *Stachys* by the 1790s)

*Ziest* (German)

### *Stachys floridana* (of Florida)

Florida betony

Florida hedge-nettle [hedgenettle]

knotroot

***Stachys tenuifolia*** (thin-leaved)

épiaire (Quebec)

slender-leaf betony

smooth hedge-nettle

Pliny wrote of what we now call *Stachys officinalis*, “The Vettones in Spain discovered the plant called *vettonica* in Gaul, *serratula* in Italy, and *cestros* or *psychotrophon* by the Greeks, a plant more highly valued than any others” (Meyer et al. 1999). Along with that species, two others were famous among Europeans before they arrived in the New World—*S. palustris* and *S. sylvatica* (Fuchs 1542, Linnaeus [1753] 1957, Dobelis 1986). Two well-known English names of these were betony and woundwort, and all were renowned as treatments for sores and open wounds.

The plants were not simply known as medicines. Most, perhaps all, species have enlarged tubers that were used as food from Europe to Asia before the New World was discovered. John Lightfoot, in his *Flora Scotica* of 1777, wrote of *S. palustris* tubers that they were “sweet, and in times of necessity...eaten by men, either boiled, or dry’d, and made into bread.” Fernald et al. (1958) had not tried that species, but spoke highly of related *S. hyssopifolia* in New England. They found the nutty tubers “white and as good a nibble or salad as one could wish.”

Although Hocking (1997) put *S. sieboldii* and *S. affinis* in synonymy with *S. floridana*, Wunderlin (1998) did not consider them the same species. Presumably, in spite of that, Hocking’s (1997) comments still apply to the Florida plants; he considered *S. floridana* edible, and thought the tubers had a taste similar to cauliflower. In France, the mint (called either *S. sieboldii* or *S. affinis*) is named *crosnes de Japan*. That name was given because the plants were introduced in 1822, 1886, or 1882 (there are conflicting dates recorded), into the French town of *Crosnes* near Paris (Hedrick 1919, Larousse 1987). Paradoxically, they then became known for the French town and for Japan.

No record has been located of *S. tenuifolia* being eaten, but perhaps it too was used; *S. floridana* tubers are eaten in Georgia (Von Reis 1973). Among the Meskwaki of Iowa, *S. tenuifolia* was made into an infusion to treat colds, and acted as an emetic (Moerman 1998).

Hocking (1997) said that the tubers of *S. floridana* contain stachydrine and stachyose. Those and many other chemicals are known from *S. sieboldii* and related species, and presumably from both Florida species (Kato et al. 1979, Derkach et al. 1980, Kobzar 1986a,b, Kobzar’ and Nikonov 1987, Greutert et al. 1993, Miyase et al. 1996). Other studies have indicated that chemicals from *Stachys* are useful as antioxidants and to treat jaundice (Voitenko et al. 1990, Couladis et al. 2003).

***Stachytarpheta*: Blue Porter-Weed**

(From Greek *stachys*, a spike, and *tarphys*, thick, referring to the flower spikes)

When I arrived in Florida in 1970, one of the first new plants that I learned was called blue porter-weed (Small 1933, Baker 1938). Most of the people I met in Florida and Jamaica simply called it “porter-weed.” Scientifically, it is *Stachytarpheta jamaicensis*.

Maybe the hard-core drinkers and connoisseurs among those I talked with knew what a “porter” was, but I did not. Indeed, I doubt many of them knew how we got the word “porter” in our language. Porter is a dark brown beer with a bitter taste that is brewed from malt partly charred or browned by drying at high temperatures. The term is a shortened form of “porter’s ale” or “porter’s beer,” and dates in English literature from the early 1700s. Originally, the brew was a cheap alcoholic drink consumed largely by porters and other laborers in England. “Porter-house steak,” and “Porter-house chop” were derived from the establishments who sold these cuts to be eaten along with the “brown, clear, bitter, and wholesome”

*Stachytarpheta jamaicensis*. Drawn by  
Shih-Huei Chen. From Chen and Wu  
2002.

brew. The descriptive name “stout” is a strong form of Porter.

The connection to beer and these plants is not immediately obvious. However, *Stachytarpheta* came to be called blue porter-weed because it was used to make a mildly alcoholic beverage used for reasons other than just medicine (Morton 1968b). Still, porter was not the only beverage made of these herbs, and at one point the leaves were exported from Brazil to Europe as “Brazilian tea” (Standley 1920–1926). Not only was *Stachytarpheta* used as a tea substitute, but also as an adulterant for tea. The beverage was consumed simply for its taste and also as a medicine. Various people have claimed that the tea was anthelmintic, cathartic, emetic, an emmenagogue, used to treat baldness, bronchitis, chronic hepatitis, dropsy, erysipelas, fever, pneumonia, stomach problems,

ulcers, venereal disease, worms (especially in children), and yellow fever. Blue porter is considered cathartic, diaphoretic, digestive, a drink for cooling the blood, a bath to reduce fever in children, emetic, an emmenagogue, a possible abortifacient, to relieve constipation, effective in ritual bathing, a sedative (in nervous disorders, or simply against insomnia), stimulant, and tonic (Standley 1920–1926, Martínez 1969, Duke 1972, Petersen 1974).

Just how much of this use should be attributed to *Stachytarpheta* and not the related *Verbena* is not clear. The two genera have been intermixed and confused since Europeans arrived in the New World. Linnaeus ([1753] 1957) even called blue porter-weed *Verbena jamaicensis* (Jamaican verbena). One must wonder if the common names Jamaica vervain (Bahamas, USA, Europe), *verbena de Jamaica* (Spanish), and *zapane de la Jamaïque* (French) are indigenous or simply translations of Linnaeus's binomial. However, other common names reveal the extent of confusion between *Verbena* and *Stachytarpheta*.

When Europeans arrived in the New World, they brought with them an old tradition of using *V. officinalis*. That species and *S. jamaicensis* are both in the Verbenaceae, both are herbs, both have small blue flowers in spikes, and they generally look alike. Use of *V. officinalis* dates to at least the Celts, early Germans, and Romans (Dobelis 1986). The common name “verbena” and its variants appeared in English literature by the 4th century A.D. Some of the older spellings were *verueyn* (A.D. 300–500), *verveine* (A.D. 300 and 600), *warwayn* (A.D. 400), and *vervin* (A.D. 500–600). In 13th-century French it was *verveine*, and in Italian it was *vervena*. Those varied spellings spawned both “verbena” and “vervain” in English. Leonard Fuchs (Meyer et al. 1999) reported in 1542 that physicians were calling the European plants by the pharmaceutical names *verbena supina* (prostrate verbena) and *sacra herba* (holy herb). Other 16th-century names included *sacra herbe*, common vervaine (English), *Eisenhart* or *Eisenkraut wieble* (female iron heart or iron-herb, German), *iserkruyt wijfen* (female iron herb, Dutch), *veruaine femelle* (female verbena, French), and *verbenaca femina* (female vervena, Italian). This plant was part of the religious traditions of the pre-Christian people, and so the missionaries dubbed it “herb-of-the-cross,” claiming that it had staunched Christ's wounds on Calvary.

When people arrived in the New World, they found another plant. They began comparing the new one with the one from the Old World. English speakers said bastard vervain (Jamaica) or vervain [also rendered as verryvine, *veng veng*, *vèven*, vervine, verbain] (Caymans, Jamaica, Montserrat, Barbados, Belize). In Portuguese, it became *gervão verdadeiro* (true vervain, originally *Verbena officinalis*, *gervão* from *urgebão*, both from *verbena*, Brazil). Those speaking Spanish said *verbena* (Veracruz, Hispaniola, Puerto Rico, Venezuela, Panama), *verbena azul* (blue verbena, Nicaragua), *verbena cimarrona* (wild verbena, Cuba), or *verbena mansa* (tame verbena, Hispaniola). Creole French rendered it as *vèven* [*gwo vèven*, big vervain; *vèven blanc*, white vervain; *gwan vèven*, old vervain; *vèven ble*, blue vervain; *vèven violet*, blue vervain] (Haiti, Trinidad), *verveine* (Haiti, Dominica), *verveine [a] queue de rat* (rattail verbena, Hispaniola), and *verveine bleue [morada, violette]* (blue vervain, Hispaniola).

Several other names show European influence in a less pronounced fashion. The Dutch *ijzerkruid* (iron herb, Suriname) and *isri-wiwiri* (iron herb, Sranan, Suriname) hark back to the mid-16th century names. The same is true of *zèb sacré* (sacred herb, Haiti),

although at first glance it might seem that this was just one of the many religious plants of Haitian voodoo (Beauvoir et al. 2001).

Some of the other common names show less European influence. To English-speaking people it is simply a blue flower (Bahamas, Jamaica, Montserrat) or blue flower vine (Jamaica, Montserrat). Several people note the similarity of the inflorescence to a tail and say *bretónica* (little tail, Puerto Rico) or *cola de millo* (millet tail, Panama). In much of the Americas, it is *chilillo* (Mexico, Central America). Literally *chilillo* is “little chile,” but is widely applied to a variety of plants, usually denoting a small bud or flower.

Several of the indigenous names are either untranslated or obscure in meaning. These include *kuribiu ákkuani* (Carib, Dominica), *kuiékuiéit* (Carib, Dominica), *lenga di baca* (cow tongue, Dutch Antilles), pound-cake bush (British Antilles), *rattestaart* (rat-tart or cake, Dutch Antilles), *rinchão* (based on *rincho*, the voice of a horse, or “big whinny,” Brazil), rooster-comb (British Antilles), and *simbunugit* (Cuna).

However, a use rarely recorded in the literature is indicated by the names *ibinxiu* (*ibin'*, placenta or umbellical cord, *xiu*, herb, Maya, Belize) and *talche* (*tal*, touch, *che'*, tree, Maya, Mexico). Surely, those names developed because of the use of *Stachytarpheta* in childbirth to wash the hands and to bathe the newborn child as well as to groom the mother before and after giving birth (J.L.Tapia, personal communication 2002). A similar use extends into Veracruz (Vásquez and Jácome 1997). The names woe vine (British Antilles), eyebright (Montserrat), and wurra weed (wurra=worry, Virgin Islands) may all allude to that application.

The chemical constituents of *S. jamaicensis* include the glycoside stachytarphine, choline, three flavonic glucuronides, iridoid ipolamiide, and the phenylpropanoid glycoside verbascoside (Willaman and Li 1970, Duret et al. 1976, Wong 1976, Melita-R. and Castro 1996, Roengsumran et al. 2002). The related *S. cayennensis* contains less than 1% essential oils citral, geraniol, and salicylic acid. The more recent studies of the chemistry of blue porter-weed have concentrated on bioactivity. These studies found extracts of the plants to be anti-inflammatory, anti-diarrhetic, antinociceptive, active against intestinal worms, microbes, and insects, to inhibit gastric acid secretion, and to promote sedation and analgesia (Robinson et al. 1990, Almeida et al. 1995, Melita-R. and Castro 1996, Rodriguez and Castro 1996, Vela et al. 1997, Schapoval et al. 1998, Chariandy et al. 1999). Not only were the plants useful for humans, but also for their dogs (Lans et al. 2000).

More recently, people have decided to cultivate *Stachytarpheta*. In the early 1980s, with the trend to cultivate Florida native species, wild plants from southern Florida were brought into nurseries. These herbs were propagated and spread across the state. Then, people began noticing that their cultivated plants were different from those in the wilder parts of southern Florida. When they looked more closely, they found that they had propagated and sold *S. urticifolia* from the Old World, and not our native species (cf. Moldenke and Moldenki 1983). Now, the Florida native, *S. jamaicensis*, has been discovered as an exotic plant in Taiwan (Chen and Wu 2002). Even when we humans try to do things right, we often mess them up. I cannot help but recall that old phrase from Robert Burns's (1785) poem, “The best-laid schemes o' mice an' men Gang aft a-gley.”

*Staphylea*

(From Greek *staphyle*, a bunch of grapes, referring to the inflorescence)

***Staphylea trifolia*.** From Britton and Brown 1897.

*Klappernuss*, *Pimpernuss* (*klappern* and *pimpern*, rattle, *nuss*, nut; *Pimpernuss* used for both *Staphylea* and pistachio, German) *pistacchio falso* (false pistachio, Italian) *staphylier* (French)

***Staphylea trifolia*** (three-leaved)

*bakokó* (Koasati)

[American] bladder nut [bladdernut] (used for the plant by 1741, comparing the inflated fruits to the bladder; “bladder” from Old English *blaedre* and other Teutonic languages)

The first name appearing in the literature for the European species (*Staphylea pinnata*) was *Staphylodendron*, published by the French physician Jacques Daléchamps (1513–1588) in his *Historia generalis plantarum* (General History of Plants) appearing in 1586–1587. Daléchamps’s name for these plants translates to “tree bearing a bunch of grapes.” Gaspar Bauhin did somewhat better in 1650–1651 with *Pistacia sylvestris* (forest pistachio). At least Bauhin noted that the fruit was edible and that people considered it essentially a wild pistachio (*Pistacia vera*).

Not long after Bauhin’s publication, a list of plants cultivated in Holland appeared. That book, written by Paul Hermann (1646–1695), was *Hortus academici Lugduno-Batavi catalogus* (Catalog of the Garden at the Leiden Academy) and published in 1687. Included was a plant he called *Staphylodendron virginianum trifoliatum* (grape tree from Virginia with three leaflets). Twelve years afterward Robert Morrison (1620–1683) wrote about a collection in northern France and called the same plants *Pistacia virginica sylvestris trifolia* (wild Virginia pistachio with three leaflets).

Linnaeus knew both species from cultivation. He had studied the central and southern European species at both the *Hortus Cliffortianus* and the *Hortus Upsaliensis*. American plants he knew only from the former garden. In 1753, Linnaeus gave binomials to both, with *S. pinnata* for the European plants and *S. trifolia* for the American plants. Subsequently, others were found and the genus contains 11 species in the north temperate zones (Mabberley 1997). Seeds of the American species, like its European relative, contain a sweet oil and are eaten like pistachios (Hedrick 1919). No reference has been found to anyone who has actually tried them recently, but several groups in the “eastern States” ate them (Yanovsky 1936, King 1984).

Few records of people using these shrubs have been found. In the woodlands of New England, the Iroquois took an infusion of *S. trifolia* mixed with other plants for rheumatism, an infusion of bark for sores, as a wash for swollen breasts, and to keep children from crying (Moerman 1998).

In Iowa, the Meskwaki considered the seeds sacred and used them in rattles and in their medicine dance (King 1984). They also used the branches to make pipe stems.

### *Stenandrium*

(Christian G.D.Nees named this with Greek *stenos*, narrow or tight, and *andros*, anther, an allusion to the stamens, which are pressed against each other in pairs)

*Stenandrium dulce*. Drawn by  
P.N.Honychurch.

*Stenandrium dulce* (sweet, although this reference is obscure)

*shaawe hope* [sawló:pî, sawloopi] (raccoon's liver, from shape of leaf, Mikasuki); *wotkolopî* [wotko impalko] (raccoon's liver; *wotko*, raccoon, *em*, its, *lope*, liver, Creek)  
[sweet] shaggyleaf (Florida)

The Miccosukees believe that babies who dream about a raccoon or opossum sometimes become ill. To calm the children, a bag containing *ayekche-hatke* (*Panax quinquefolius*), *to:li* (*Persea borbonia*), *acini* (*Juniperus virginiana*), and *shaawe hope* is placed around the child's neck. The last is used because of the relationship between its name and the cause of the ailment. The plant also is used to treat "Hog Sickness" (periodic unconsciousness with shallow and slow breathing) (Sturtevant 1955). Perhaps the Miccosukee use the plants in other ways because Bennett (1997) was told *shaawe loope* was used in an undisclosed medicine, and Snow and Stans (2001) listed the plant and its names but gave no use.

The common name "rattlesnake-flower" (Florida) was attributed to the Seminoles in 1919 by Sheehan, who claimed that they drank a hot decoction as a remedy for rattlesnake bite (von Reis and Lipp 1982). He said they called it *sin-ty-etsee* (may be *sentihyce*, little platform).

I must wonder about how long the Seminoles have been using these plants. Their malady involving raccoons and opossums must be old, but they have not been in contact with *Stenandrium* that long. The U.S. variety, *S. dulce* var. *floridanum*, is endemic to southern peninsular Florida and the Florida Keys. From there, the species is disjunct to southern South America, having first been collected in Chile. No other species occurs in mainland North America east of Texas, but there are several *Stenandrium* species endemic to the Bahamas and Antilles (Leon and Alain 1957–1963, Correll and Correll 1982, Liogier and Martorell 1982). At least the common names of *S. tuberosum* in Puerto Rico (*mata esperitista*, spirit bush; *yerba maravilla blanca*, white miracle herb) suggest use (Liogier and Martorell 1982).

### ***Stillingia*: Corkwood and Queen's Delight**

(Linnaeus named the genus after the British naturalist Benjamin Stillingfleet, 1702–1771)

*Stillingia sylvatica*. From Britton and Brown 1897.

Almost as soon as I arrived in Florida, I began exploring areas that were still wild. In nearby ponds, I found a shrubby herb that had inconspicuous flowers. The stem was soft and corky, and I soon learned that it was corkwood. Old-timers in southeastern Florida told me that the stems floated nicely and made good corks for fishing. Alvin Wentworth Chapman had named the pond plants *Stillingia aquatica* (of wetlands) in 1860.

I soon learned that people of European descent were not the only ones who thought the soft, buoyant stems were useful. To the Seminoles, the plants were *ahisókpi* (*ahi*, tree, *sokpi*, spongy, Mikasuki). Sometimes they use its alternate equivalent name, *taktsókpi* (*takfi*, shrub, *sopki*, soft). The Creeks also said *Stillingia* was *itotahátka* (*etotale*, dead tree, *hvtke*, white, Creek).

It was not long before I found another species in the uplands of pine flatwoods. The pineland species was the one named by Linnaeus when he created the genus in 1767, *S. sylvatica* (of the woods). Since at least the late 1800s, that species has been known as “queen’s delight” (Chapman 1897).

Although we are now taught that “queen” applies to a female of royal lineage, it was not always so. Originally, queen came from the Old English *cewn*, which meant simply “woman.” Just when the Florida plants now called “queen’s delight” came to be that is uncertain, but it always had an earthy connotation. That name alluded to an imagined similarity between the inflorescence and male genitalia. The name cock-up-hat [cocyshat], used in the Carolinas (Morton 1974), has a similar meaning.

Because the herbs are mostly confined to the southeastern United States, they have few names in languages other than English. Germans call them *Talgbaum* (tallow tree), although that has developed because of their relationships with the genus *Sapium*, which is usually called tallow wood. *Stillingia* is mostly known as “corkwood,” whether it is *S. aquatica* or *S. sylvatica*. Sometimes *S. sylvatica* is called by the descriptive terms nettle potato or silver leaf. “Nettle potato” must refer to the caustic, vesicant nature of the raw sap, while “silver leaf” surely alludes to the sometimes white-striped leaves. That chemical trait may also be why it is called Indian flea root in Louisiana, where it was placed to repel those pests (von Reis 1973).

Two other common names in the southeastern states refer to medical uses—marcory, and yaw root. Although the first term resembles the English “marcor,” from Latin *mar cere*, to decay or become emaciated, it probably is not related. More likely, “marcory” is a mispronunciation of “mercury.” Since the “standard” medical treatment for syphilis in the 1800s was to use the poisonous metallic element, the name was transferred to plants with similar functions. Millsbaugh (1892) recorded that *Stillingia* extracts were considered “an absolute specific in syphilis, entirely superceding the use of mercury.”

The name yaw root notes that the plants were used to treat an infectious contagious tropical disease caused by the spirochete *Treponema pertenue*. “Yaws” is a Cariban word related to *yáya* in Calinago, an Arawakan language of the Lesser Antilles and Central America. The name was applied by 1679 to this disease, which, like syphilis, is characterized by ulcerating lesions with later bone involvement. The malady, thought to have come from sub-Saharan Africa, is closely related to the variant of syphilis called “pinta,” which is caused by *Treponema carateum*. Causal organisms and symptoms are so similar that “pinta” was probably the original “yaws” in the New World (Desowitz 1997). Since about 1803, English-speaking people have also called the malady “frambesia” (from French *framboise*, raspberry) because of the appearance of the lesions.

Although Americans quickly adopted *Stillingia* as a remedy for venereal diseases, the native Americans did not use it as uniquely for that problem. Bartram ([1853] 1909) said that during the 1770s the Creek, Seminole, and Cherokee had “a high estimation of a species of either *Croton* or *Styllingia*, I am in doubt of which, as a cathartic.” Indeed, later work among these people and others in the southern states showed that was but one of the uses for these plants. True, among the Cherokee a decoction or tincture of root was used for venereal disease (Hamel and Chiltoskey 1975). However, given the late recording of that information, it probably reflected a heavy non-Cherokee influence. More likely indicative of original uses were those recorded among other people.

The Creeks, for example, considered *Stillingia* abortifacient and cathartic. Creek women washed in root extracts after giving birth, and drank the liquid. A cold infusion was also taken by men to regain potency (Swanton 1928a, Taylor 1940, Howard 1984). They call the plants *yalang cati* (yvlonkv, root, *cate*, red, Creek) or *yelungadjadi hiliswa* (yvlonkv, root, *cate*, red, *heleswv*, medicine, Creek).

Their relatives, the Seminoles, considered the roots antidiarrheal. Because the leaves and stems have milky juice, they call it *owa:ctafânkî* (*owa:ct*, center, *efânki*, milk, Mikasuki). Those speaking Creek call them *pisi:ká:fkatî:ko* (*pese*, breast, *kafkv*, milking, *?tekoye*, pliable). Also, a decoction of the roots was taken by babies and adults for “Bird Sickness” (diarrhea, vomiting, and appetite loss). A similar decoction of roots was taken for “Menstruation Sickness,” indicated by yellow eyes and skin, weakness, and a shaking head (Sturtevant 1955). Now, the Miccosukee healers usually admit only to using the remedy for stomachache (Bennett 1997). They are guarded in what they reveal, but they have told me that they still use the plants for women’s problems.

*Stillingia* was perhaps less important among the unrelated Kiowa who considered *knoñ-klee-a* (turtle weed) a season indicator. They considered it a rain symbol because the dry land terrapins get under it for shade (Vestal and Schultes 1939).

Basically, the native Americans considered *Stillingia* root extracts a “blood purifier.” That concept is rendered as an “alterative” in medical parlance, which means that it gradually restores the proper function of the body and increases health and vitality.

However, Murphee (1965) inferred that it was also used to indicate anemia in the Panhandle where *S. sylvatica* was still in use. Queen's delight was official in the U.S. Pharmacopoeia between 1831 and 1926 and in the National Formulary between 1926 and 1947, where it was considered cathartic, alterative, and emetic.

Porcher (1863) considered the remedy "as an alterative in scrofula, in syphilis, in cutaneous diseases, in chronic hepatic affections, and in the composition of diet drinks; it adds to the efficacy of sarsaparilla." He went on to note: "A tincture is made with the root two ounces, of diluted alcohol a pint. Dose a fluid drachm. A decoction is made of the bruised root one ounce, water one and one-quarter pints. Boil to one pint. Dose, one or two fluidounces several times a day; an overdose is cathartic or emetic." During the same time, the plant in the Old South was "widely used to treat constipation; to induce vomiting, and as a remedy for syphilis, skin and pulmonary diseases, and liver ailments. A rubdown of boiled, mashed roots was used to treat women suffering from menstrual irregularity" (Krochmal and Krochmal 1973). In the Carolinas, a root decoction was used to cure boils and treat stomachaches, and it was an ingredient in "S.S.S. TONIC" (Morton 1974). Although it is not specifically stated in the literature, one of the properties of the remedy was as an antispasmodic. That trait would account for several of the historical uses.

The roots fell into disrepute after the 1940s, and were rarely used. However, some trade continued with them (Christensen 1946). Then, after a hiatus, they again became popular during the current herbal renaissance. There are dozens of companies on the Internet advertising them for a variety of ailments. For example, one company (abchomeopathy.com) recommends the plants for coughs, sore throat, genital problems, and syphilis. Herbal Alternatives (herbal-alternatives.com) considers queen's delight alterative, depurative, expectorant, diaphoretic, sialagogue, astringent, and antispasmodic. Most of the modern companies note that *Stillingia* was one of the ingredients in the infamous Hoxsey anticancer compounds (cf. chatlink.com/~herbseed, herbalalternatives.com). That use has been discredited, although others have not. Moore (1989) recommended the preparation for skin problems and coughs, and to aid in recuperation from lung problems.

There are several bioactive chemicals known from *Stillingia*, including the alkaloid stillingine that was discovered about 1882 (Millsbaugh 1892). The plants also contain apocinide, calcium oxylate, echiine, gnidilatin, hydrogen cyanide, phorbols, especially 5-beta-hydroxy 12-deoxy phorbol, prostatin, resin, silvacrol, tannin, and volatile oils (Felter 1922, Moore 1989, 2002). In spite of the thriving trade in the herbal market, no modern chemical studies seem to have been published on the genus.

*Stillingia sylvatica* has a wide range. It is known from southeastern Virginia to Florida, Texas, and New Mexico, north to Oklahoma, Kansas, and Arkansas. It was collected by C.W.Short in the "Barrens" of Kentucky in 1840, but apparently it has not been seen there since (Browne and Athey 1992). In spite of that range, *Stillingia* populations have steadily declined during the past few decades. Because of collection for the herbal market and habitat loss, *S. sylvatica* is now a rare plant. The species is so uncommon it was considered for listing as endangered in the late 1970s. Herbal doctors on the Big Cypress Seminole reservation lamented the disappearance of plants there during our research between 1998 and 2001. So, whenever we found new localities with plants, we made sure they were informed.

“Use it or lose it,” is an admonishment that I heard often when growing up. Now, we learn that, by using our plant resources, we may well lose them. Sometimes, the brevity of old sayings underestimates the problems of the modern world.

### *Strumpfia*

(Nicolaus Jacquin named this genus for Karl Strumpf, a professor in Halle during the middle of the 18th century)

***Strumpfia maritima*** (of the sea, as it grows near coasts)

*bai no bolbe* [*bai no bolbera*] (go and do not return, Dutch Antilles)

*faux rosmarin* (false rosemary, Haiti); *romerin bord du mer* (seaside rosemary, Guadeloupe); *romero falso* (false rosemary, Cuba)

grankini (Bahamas)

*lirio* (lily, Puerto Rico)

pride-of-Big-Pine (Florida)

seaside Strumpfia (a book name, Bahamas)

***Strumpfia maritima*.** a. Old flowering branch, b. Young flowering branch, c. Inflorescence, d. Flower, front-side view, e. Flower, longitudinally dissected, f. Floral diagram, g. Fruit, smaller than life (left) and enlarged (right). Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Jacquin named this species in 1760 from his collection in Jamaica. It is a monotypic genus, and the species is found in the Bahama Islands, Cuba, Jamaica, Puerto Rico, Yucatan, and the Lesser Antilles to the Netherland Antilles off South America (Boldingh 1909, 1914, Liogier 1962, Fournet 1978, Correll and Correll 1982).

The whole plant is stimulant and has been used against bites of poisonous animals. In severe fevers with delirium, *romero falso* is mixed with quinine (Roig 1945). In Curaçao, a weak decoction is used to treat colds, stomachache, and kidney stones. A stronger decoction permanently sterilizes women (Morton 1981).

The plant is burned in the Bahamas to repel mosquitoes (Von Reis 1973). In Curacao, it was formerly burned outside homes to drive away bad luck (Morton 1981).

### *Stylosanthes*

(Olaf Peter Swartz named this from Greek *stylos*, column, and *anthos*, a flower, because of the column-like calyx tube)

#### *Stylosanthes hamata* (hooked at the end)

- Caribbean stylo
- cheesy toes (Jamaica)
- chichibe* (something in the path that sticks, Maya, Yucatan)
- comino sabanero* (savanna dwarf, Cuba)
- donkey weed (Jamaica, Virgin Islands)
- lady's fingers (Jamaica)
- Lucy Julia (Cayman Islands)
- mother-sea-gel (Virgin Islands)
- pencil flower (Florida, Bahamas, Puerto Rico, Jamaica, Cayman Islands)
- petit trefle* (little clover, Guadeloupe, Martinique);
- trefle jaune* (yellow clover, Guadeloupe, Martinique)
- pinda shimaron* (wild *pinda*, Dutch Antilles); *wilde pinda* (wild *pinda*, Dutch Antilles)
- tebenque* (probably Taino, Cuba; also used for *Evolvulus* and *Pectis*, which see)
- zarzabacoa enana* (dwarf *zarzabacoa*, which is a variant of *guasabacoa*, a Taino word for *Desmodium*, Puerto Rico)

*Stylosanthes* was named by Swartz in 1788. Since then, the genus has grown to 25 species in the tropical and warm parts of the world (Mohlenbrock 1958, Mabberley 1997). The species are mycorrhizal and phosphate accumulators, and plants in Australia are famous for immobilizing and killing cattle ticks.

Jamaicans used "cheesy toes" as a cold remedy and for kidney trouble (Ayensu 1981, Morton 1981). Similarly, a decoction is drunk for kidney pain in Curaçao (Morton 1981). People in the Virgin Islands give it to teething children to relieve fever (Morton 1981).

There are several related species with other recorded uses. In Mississippi, *S. biflora* is called "after-birth weed" or "squaw weed," and is used as a uterine sedative in cramps

(Hocking 1997). A decoction is also used as an emmenagogue. In the West Indies, and from Mexico to Peru, *S. viscosa*, called *comino sabanero* or “poor man’s friend,” is used to treat colds, fever, headache, kidney disorders, and nervous problems (Hocking 1997). From Guatemala and Honduras to the Guianas, *S. guayanensis* is *yerba del campo* (countryside herb), and an infusion is used for “pains in the side” (Hocking 1997).

### ***Suriana*: Bay Cedar**

(Named for Joseph Donat Surian)

In 1689, King Louis XIV sent two Frenchmen to the Caribbean where they explored for medicinal plants on Martinique, Guadeloupe, and Haiti. The best known of the two is the Franciscan priest Charles Plumier. Less known is Joseph Donat Surian, the physician and pharmacist from Marseilles who accom-

***Suriana maritima*. Drawn by  
P.N.Honychurch.**

panied him. Although Surian returned to France in 1690 with a collection of plants now at Paris, he died in 1691. Perhaps because of Surian’s death, Plumier named *Suriana* after him in 1703. *Suriana maritima* is now “bay cedar” (Bahamas, Florida).

Relationships of this beach shrub have been a mystery since its discovery. Plumier wrote of it, *Suriana foliis portulacacae angustis* (*Suriana* with narrow leaves like *Portulaca*). Hans Sloane said, *Thymelaeae facie frutex maritimis tetraspermos* (four-

seeded marine shrub that resembles *Thymelia*). Leonard Plukenet penned, *Arbor americana, solids foio* (American tree with leaves like willow). Linnaeus did not commit himself, simply using *Suriana maritima* (marine).

That “bay cedar” grows along ocean bays is obvious. Indeed, it grows along beaches around the tropics, in southern Florida, Bermuda, the Bahamas, the West Indies from Cuba to the Grenadines, Aruba, Bonaire, and Curaçao, and from Yucatan and Belize south to northern Venezuela. The shrubs also line beaches in the Caroline Islands, Tahiti, Guam, and other Pacific islands, and also in East Africa, Madagascar, islands in the Indian Ocean, Melasian islands, and northern Australia.

My problem with the Florida name was “cedar.” I saw no obvious similarity to a gymnosperm of any kind. Others disagree, and say, “It does indeed resemble a refined conifer” (Anonymous 2002). To me the leaves are more like *Portulaca* or *Thymelia* or *Salix* as noted in the 1600s and 1700s. It took a long time before I finally discovered that the appellation “cedar” was a reference to the fragrance of the crushed leaves. At least to my nose, the odor is subtle and best enjoyed from bruised leaves in an almost-closed hand.

People long before me had known of that odor. To the Taino of Cuba, the plant was *cuabilla* (little *Amyris*) or *cuabilla de costa [playa]* (coastal [beach] little *Amyris*). Both names compare the fragrance with that of the much stronger *Citrus* relative (see *Amyris*: Torchwood). Other people simply say the plant is *incienso* (incense, Cuba), a compliment in Latin America. A similar compliment compares this New World plant with one from the Mediterranean. People say that *Suriana* is *romein noir* (black rosemary, Guadeloupe, Martinique), *romero* (rosemary), or *romero de mar* (sea rosemary). All of those names compare the shrubs with *Rosmarinus officinalis*, the popular European medicinal spice.

Not all names refer to the odor. Moreover, several of bay cedar’s other names note uses not found in the literature. Apparently indicating use as a flavoring for food are *crisse marine [christe marine]* (marine cress, Haiti), *oseïlle bord de mer* (seaside sorrel, Guadeloupe, Martinique), and *salcedo* (salty, or a plant used in sauces). Allusions to medical uses are strangely few since many people use it. One apparent notation of medicine is *pantsil [pantzil]* (*pats’*, smooth, *pats’il*, increase strength, Maya, Yucatan). Probably, *temporana* (early riser, Puerto Rico) has a similar implication. While any relationship is obscure, medicinal use may be inherent in *palo corra* (running or blowing [as wind] tree, Curaçao, Venezuela) and *perce-pierre* (stabs Peter, Haiti).

Elsewhere the stems have been made into a *cucharo* (spoon, Venezuela) and branches used as thatch-leaf (USA). Maybe tassel plant (Bahamas) indicates an ornamental or *incienso* use, but Workman (1980) thought it was simply because the leaves were clustered in “tassels” at the end of branches.

The heartwood is dark red or maroon, hard, heavy, polishes well, and is used for small articles (Morton 1981). Use of the wood perhaps is related to the common name *guazumilla* (little *guazuma*, Dominican Republic). The Taino name *guazuma* or *guásima*, refers to *Guazuma ulmifolia* (Malvaceae). That and several other Caribbean trees and shrubs bear variations on the old Taino name. It is tempting to conclude the same use for them as for the original. Of *guásima*, Bartolome Las Casas wrote, “*De este arbol solo sacaban fuego los indios: tomaban dos palos de él, muy secos, el uno tan gordo como dos dedos, e hacian en él con las unas o una piedra una mosquecita, e ponian este palo debajo de los pies, e el otro palo era más delgado, como un dedo, la punt a redonda,*

*iduesta en la muesa, con ambas palmas de las manos traianlo a manera de un taladro, ésti con mucha fuerza*" (From this tree the Indians only made fire. They took two branches of it, very dry, with one the size of two fingers, and they made in it with the fingernails or a rock a little groove, and put this stick between their feet. The other was narrower, like a finger, the point rounded, and of this in the notch, with both palms of the hands twirled it like a drill, with great force). Since *Suriana* is named after *Guazuma*, it too may have been used for making fire.

Another name for these shrubs is *jovero* [*jobero*] (Dominican Republic). That is an allusion to the *jobo*, a Taino name for *Spondias* (Coll y Toste 1972). Any relationship between the two is cryptic because they have no similarities in fruits, habit, or places where they grow. Another unexplained name is *guitarón* [*guitarán*] (presumably the same as *guitarrón*, rascal, good-for-nothing, Puerto Rico).

Not everyone agrees that *Suriana* is good-for-nothing. Bahamians treat mouth sores with it (von Reis and Lipp 1982). In Cuba, the leaves and branches are used in baths against rheumatism, a decoction of bark and leaves is used against sores, and powdered leaves are mixed with *atole* to treat bloody flux (Roig 1945). In Hispaniola, the bark and leaves are used against rheumatism, and to cure sores (Liogier 1974). In Inagua, people boil roots or twigs and inhale the vapor or hold the decoction in the mouth for toothache or to heal mouth sores (Morton 1981). In Mexico, Martínez (1969) says, "*es antidoto contra las morduras de cualquier pescado, llagas y heridas, fogazos de la boca y lengua; cámaguas de sangre, postemas e incordios*" (it is antidote for bites from all kinds of fish, sores and wounds, canker sores of the mouth and tongue, bloody fluxes, abscesses, and tumors). Specifically in Yucatan, a decoction of leaves and bark is used to clean sores, and dried powdered leaves are taken in cornmeal *atole* for rectal hemorrhages (Morton 1981). As far away as the Pacific Islands, crushed flowers are mixed with coconut milk to stop diarrhea and vomiting of blood (Weiner 1971, Whistler 1991).

Little seems to be known of the chemistry of the genus, but Watson and Dallwitz (2000) note that it has no cyanogenic compounds, no saponins, and no sapogenins. Hershenson and Quimby (1969) and Mitchell (1971) did find triterpenes and flavonol glycosides. Those classes of chemical would likely be responsible for many of the historical medical applications.

The mystery about relationships of this plant that began in the 1600s has barely abated. *Suriana* was included in the Simaroubaceae by Bentham and Hooker (1883) along with other families in the order Sapindales. Many floras since have followed that placement. Cronquist (1981) did not agree, and put *Suriana* with *Cadellia*, *Gulfoylia*, and *Stylobasium*, in the Surianaceae. There have been several convincing arguments for placement in a separate family. Some continued thinking *Suriana* was close to the Connaraceae, Sapindaceae, and Chrysobalanaceae. Others disagreed and put the Surianaceae in the Rosales, as did Cronquist.

Only within the past few years have people generally begun recognizing the family Surianaceae. Most include four genera, and now those are *Suriana*, *Cadellia*, *Gulfoylia*, and *Recchia*. *Stylobasium* now seems to be part of another lineage (Watson and Dallwitz 2000). Study of molecular genetics (Fernando et al. 1993, Kajita et al. 2001) and embryology (Heo and Tobe 1994) suggest monophyly of the family and kinship to the Polygalaceae and Fabaceae. Art Cronquist would have been happy to know that he was

right putting *Suriana* in the Rosales (Cronquist 1981). Or, maybe he would have just grinned and said, “Of course!”

### ***Swietenia*: Mahogany**

(Named for Gerarde L.B. van Swieten)

There is a mahogany cross dated 1514 in the cathedral at Santo Domingo (Ciudad Trujillo), Hispaniola. In addition, the church contains other carved mahogany woodwork more than five centuries old (Little and Wadsworth 1964). Those items confirm the importance of these trees to indigenous people and to early European settlers. Given that antiquity, it seems odd that no common name for *Swietenia mahagoni* appeared in print until the 1600s, especially because names from three areas were in common usage.

In 1671, John Ogilby told about the Jamaican trees with “most curious and rich Woods, as Cedar, Mohogeney, Lignum-vitae.” Languages other than English also use the Caribbean word for the trees. *Swietenia mahagoni* is also *Mahagoni* (German), *mahonie* (Dutch), *mahagoni* (French), *mogano* [*mogogane*] (Italian), and *mogno* (Portuguese). The Portuguese word *mogno* is said to be from an indigenous language (Ferreira ca. 1978), perhaps Taino. The Taino words *maga* or *magua* mean fertile lowland or plains. A related word *mahok*, which is akin to Taino *maho*, refers to trees with strong bast fibers (Coll y Toste 1972). In Suriname, *S. mahagoni* is still *mahoni*.

Mark Catesby gave the world the first illustration of mahogany. He was born and educated at Essex, England before he went to Virginia in 1712 at age 29. Wealthy and influential patrons back in Europe were so impressed with the plants he sent that, in May of 1722, Catesby was sent to Charles Town, South Carolina (Reveal 1992a). On a trip to the Bahama Islands Catesby drew “The Mahogony tree” (Catesby 1734–1747). Linnaeus traveled to Oxford in August of 1736 partly to examine Catesby’s specimens and drawings. Subsequently, Linnaeus published *Cedrela mahagoni* in 1759 based on Catesby’s drawing.

It was only the following year that Nikolaus Joseph Baron von Jacquin, director of the botanical garden in Vienna, coined the generic name *Swietenia* for this tree. Jacquin named the tree for Gerarde L.B. van Swieten (1700–1772), a Dutch physician for Empress Maria Teresa of Austria. He wrote the name as “Mahogoni,” although Linnaeus had it *mahagoni*.

We are left with the question of why a tree with virtually no bast fibers got a name pinpointing them. Perhaps there was a confusion of indigenous names, with the *maho* having good bast fibers, and Europeans mistaking it for the name of this tree (see *Trema*: Nettle-Tree). Confusion seems likely because there is another Taino word that still means *S. mahagoni*. Cuban Tainos called the tree *caoba* [*caobo*] (Guerrero, Tabasco, Yucatan, Oaxaca, Cuba, Puerto Rico), and that became its name in Spanish. That Taino name remains in the Caribbean as *caoba americana* (American mahogany, Puerto Rico), *caoba de Cuba* (Cuban mahogany, Cuba), *caoba de Santo Domingo* (Dominican mahogany, Puerto Rico), *caoba dominicana* (Dominican mahogany, Puerto Rico), *caobilla* (little mahogany, Cuba), *palo de caoba* (mahogany tree, Puerto Rico), and *kuba* mahogany (variant of *caoba*, Cuba).

One of the reasons that names for mahogany are so intermingled is because people were trading two species. The original range of *S. mahagoni* was southern Florida, the Bahamas, Cuba, Jamaica, and Hispaniola. From there it was introduced into Puerto Rico and the Virgin Islands, Bermuda, the Lesser Antilles, Trinidad and Tobago, and Curaçao south through South America and elsewhere in the tropics (Little and Wadsworth 1964). Its names became mixed with those of *S. macrophylla*, which was native to much of the area where *S. mahagoni* was introduced.

Wood from the mahoganies was so important that even South American names became used in the Caribbean. A common Haitian appellation is *acajou* [*akajou*, *acaju*, *kajou*, *nacajou*]. That name came from

*Swietenia mahagoni*. (left), a. Flowering branch, b. Flower buds. c. Staminate flower, front-side view. d. Staminate flower, from below, e. Staminate flower longitudinally dissected, f. Pistillate flower, longitudinally dissected, g. Floral diagram, h. Fruiting branch, i. Leaf outline, j. Fruit, dehiscent, k. Seed. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Tupí *aka 'vú*, originally applied to wood from the Brazilian *S. macrophylla*.

The exchange of the two species also was one of the reasons that so many geographic modifiers have been added to the word mahogany. Variations using *acajou* in the Caribbean include *acajou a meubles* (furniture mahogany, French Antilles), *acajou de Cuba* (Cuban mahogany, Cuba), *acajou de Haiti* (Haitian mahogany, Haiti), *acajou de St. Domingue* [*acajou San Domingo*, *kajou sen domeng*] (Dominican mahogany, Haiti, Guadeloupe), *acajou des Antilles* (Antillean mahogany, Haiti), *acajou mahogani* (mahogany mahogany, Guadeloupe), *acajou ronceux* (bramble mahogany, Haiti), *albero di acajou* (white mahogany, Dutch Antilles), *bwa kajou* (tree mahogany, Haiti), *kajou peyi* [*pyè kajou*] ([country] wild mahogany, Haiti), and *kajou ti fey* (little leaf mahogany, Haiti).

In English, the trees are known as American mahogany (West Indies), curlet mahogany (curly mahogany, Jamaica), medura redwood (medura meant for *madeira* from Spanish, USA), small-leaved mahogan (Virgin Islands), and true mahogany (West Indies). Depending on where the tree comes from, it may be Dominican mahogany (Puerto Rico), Florida mahogany (Florida), Honduras mahogany (Florida), Jamaica mahogany (Jamaica), Mexican mahogany (USA), San Domingo mahogany (West Indies), Spanish mahogany (Trinidad), or just West Indian mahogany (Trinidad).

Speakers of Spanish say *antillen* (from the Antilles, Cuba), *echtes kuba-mahogoni* (mahogany-mahogany sprout, Cuba), and *echtes mahogoni* (mahogany sprout, Cuba). Those speaking French say *mahogany du pays* ([country] wild mahogany, Guadeloupe) or *mahogany petites feuilles* (small-leaved mahogany, Windward Antilles). People in the Dutch Antilles say *Antillen-mahogoni* (Antillean mahogany), *Cuba mahonie* (Cuban mahogany), *mahonijboom* (mahogany tree), *mogano americano* (American mahogany), and *mogano di Cuba* (Cuban mahogany).

Some other names for *Swietenia* include *cèdre des Antilles* (Antillean cedar, French Antilles), *madeira* (Spanish for wood, Bahamas, USA), *nieuxbladboom* (new leaf tree, Dutch Antilles), redwood (Bahamas), and sabica (Bahamas). The latter two names show comparison with wood from *Lysiloma* (see *Lysiloma*: Wild Tamarind).

Mexican trees are called *cóbano* (Guerrero, Michoacán, Colima), *zopilo-zontecomacuahuitl* (vulture-head-tree, in reference to the curved fruits that resemble buzzard heads from a distance, Náhuatl), *zopilote* [*tzopilotl*, *zopilocuahuitl*, *zopilotl*] (vulture [tree], Guerrero, Tabasco, Yucatan), and *palo zopilote* (vulture tree, Oaxaca).

Plants are used as street and shade trees because of their spherical crown and dense shade. However, mahogany is best known for the wood used in furniture, cabinetmaking, interior finish, and veneers. The wood is easily worked and takes an attractive polish. Much older uses, from at least the time of Catesby and Romans ([1775] 1961), are in shipbuilding, construction, and for beams. Catesby (1734–1747) compared the wood of the mahogany with oak (*Quercus*), high praise indeed from a European of the time. Romans ([1775] 1961) complained that by the time of his visit to the Florida Keys most of the mahogany had been cut. In his instructions to navigators for the region between *Cayo Hueso* (bone key, now Key West) and Matacumbe Key, he says that, because of woodcutters from Providence in the Bahamas taking the mahogany trees, “little or none now remains here.”

Less well known is that people use mahogany for medicines. Cubans use the gum exudates from the trunk as a bitter and astringent tonic and febrifuge (Roig 1945). Juices of young shoots are also used in Cuba to heal wounds and stop bleeding. Oil from *S.*

*macrophylla* seeds (*pepitas de zopilote*, vulture seeds) was used by Aztecs as a cosmetic and in the 1920s in soaps (Standley 1920–1926). People in Hispaniola use the plants to treat anemia, bleeding, chest pain, diarrhea, dysentery, fever, loss of appetite, malaria, nerve disorders, toothache, and as an abortifacient, antiseptic, aphrodisiac, astringent, emmenagogue, and to provide iron and vitamins (Beauvoir 2001).

Mahogany bark contains catechin-like compounds, and the wood contains catechin (Ayensu 1981). These flavonoids and related chemicals are also in tea (*Camellia sinensis*) and red wines (*Vitis vinifera*), and have become famous for reducing risk of heart disease (e.g., Rosenkranz et al. 2002). Seeds contain swietenine, swietenolide, and related compounds (Ekimoto et al. 1991, Mootoo et al. 1999). Those chemicals are limonoids related to those found in neem (*Azadirachta indica*), chinaberry (*Melia azedarach*), and other members of the Meliaceae and Rutaceae (Bickii et al. 2000). Those compounds have become famous as insecticides (e.g., Mootoo et al. 1999, Bickii et al. 2000), have been shown to inhibit platelet aggregation (Ekimoto et al. 1991), to inhibit human cancer cell proliferation (Tian et al. 2001), and to exhibit antimalarial activity (Bickii et al. 2000).

Sometimes the common names themselves are a “generic” category. Anything that is not known becomes part of that umbrella. For example, in Dominica, no matter whom you ask if you wanted to know what a particular plant is, the answer was almost invariably “*p’tit feuille*” (little leaf, P.Honychurch, personal communication, 2002). That is always a good generic cover-all for almost any unknown bush. She used to have an overseer who taught her more than 25 species of “*p’tit feuilles*.” So, never try to stretch the common names too far.

### *Symphoricarpos*

(From Greek *symphorein*, to bear together, *carpos*, fruit, from the clustered fruits)

***Symphoricarpos orbiculatus*.** From Britton and Brown 1898.

*pianta della perle* (pearl plant, Italian)

snow-berry [snowberry] (the European species has white fruits);  
*Schneebeere* (snow berry, German); *snøbaer* (snow berry, Norwegian)  
*symphorine* (French)

***Symphoricarpos orbiculatus*** (round)

buck-brush [buckbrush] (Kentucky)

*cate fulotv* (*cate*, red, *fulotv*, buck-brush, Muskogee)

coral-berry [coralberry] (name given by 1860, because of the red fruits)

*gu-la-ko'-kee'a* (Kiowa)

Indian-currant ("currant" came into English in A.D. 1234 as "raisins of Corauntz," from French *raisins de Corinthe*, a seedless grape from Greece; the name suggests that indigenous people ate the fruits, but no confirmation has been located; Core 1967 said of the fruits, "they are scarcely edible"; then maybe medicinal?)

*inshtogahte-hi* (*inshta*, eye, *gahte*, lotion, *hi*, plant, Omaha-Ponca)

snowberry (a form with white fruits)

*tatepa'siki* (twisted, Meskwaki)

[red] waxberry ("waxberry," a name originally given to *Myrica cerifera* by 1813, later transferred to these plants)

wolf berry (used since 1834; "wolf" is from Old English *wulf*, with similar words in German and Dutch, and related to Sanskrit *vrkas*)

*zhon-çi hi zhin-ga* (*zhon*, wood, *çi*, yellow, *hi*, stalk, *zhin-ga*, small, Osage)

*zuzecha-ta-wote sapsapa* (*zuzecha*, snake, *ta*, its, *wote*, food, *sapsapa*, black, Dakota)

I grew up calling these plants "buck-brush," a name my parents and grandparents used for them. As I floundered through the woods at night trying to keep up with my dad and the dogs as they chased raccoons, we were sometimes tripped by thickets of these shrubs. My impression was always that they were "buckbrush" because you had to "buck" or fight your way through their tangles. Surely, none of the compilers of the *Oxford English Dictionary* ever considered that possible etymology because it was too alien to their city dwelling lives.

It was during my first or second year in college that I learned the scientific name of "buck-brush." During that year, I skipped meals and did extra work to save enough money to buy a copy of M.L.Fernald's *Gray's Manual of Botany* (a 1632 pp. book for \$15). Although that was in the early 1960s, I still have a vivid memory of my sense of accomplishment as I left the college bookstore guarding my prize. From that book of wonders, I learned that "buck-brush" was known to scientists as *Symphoricarpos orbiculatus*. At the time I had no clue what a history those words revealed. The events began when John Clayton sent a specimen to Europe where they were studied by Dillenius, Gronovius, and Linnaeus.

In 1732, Johann Dillenius called them *Symphoricarpos foliis alatis* (Cluster-fruit with winged leaves). Both Linnaeus and Jan Gronovius published on them within a year of each other (1738 and 1739), calling them *Lonicera pedunculis axilliaribus capitatis* (Honeysuckle with flowers in heads on axillary stalks). Later, Linnaeus ([1753] 1957)

shortened the phrase name in *Species Plantarum*, where he coined the binomial *Lonicera symphoricarpos*.

It was only 1755 when French agronomist and forester Henri Louis Duhamel du Monceau (1700–1782) wrote on these plants in his *Traité des Arbres et Arbustes*. Duhamel adopted as a genus the one proposed by Dillenius, and created the name used today—*Symphoricarpos*.

This red-fruited shrub is native across much of southern North America. It is largely replaced in the north by white-fruited *S. albus*, which has an equally complicated history. These are 2 of the 17 species now known in *Symphoricarpos*. All but one of them is native to the Americas, and the other (*S. sinensis*) grows in China (Jones 1940, Mabberley 1997).

The only records found of people using *S. orbiculatus* are in the Missouri River region and southern Manitoba and Ontario. The Dakotas ate the berries (Yanovsky 1936). The Dakota, Ojibwa, Omaha, and Ponca steeped the leaves to make an infusion for weak or inflamed eyes (Gilmore 1919, Moerman 1998). The Meskwaki made a tea from the root which was used to expel the afterbirth, and was believed to “enable quicker convalescence” (King 1984, Kindscher 1992). The Missouri River tribes also utilized *S. occidentalis*, and their names and uses are identical for both species. The Dakota made charcoal from the wood and used it for making tattoos (Moerman 1998).

It seems likely that all of the eastern species were used because there are many more people recorded as using the related *S. albus*. Moerman (1998) lists 36 tribes using that species for medicine, fiber, food, and other purposes. Records also exist for three other species having been used by other tribes (Moerman 1998).

Hocking (1997) recorded that roots of *S. orbiculatus* roots were used as a diuretic and antipyretic, and that the roots were used as an astringent tonic. He did not say who used the plants, but presumably it was European and other settlers. Apparently, the only species that has been studied chemically is *S. albus*, and it contains saponins and tannins (Hocking 1997).

### *Symplocos*

(From Greek *symplocos*, connected, from the union of the stamens)

#### *Symplocos tinctoria* (used as a dye)

horse-sugar [horse sugar] (in use by 1864)

[common] sweetleaf (so called because the leaves were relished by cattle and horses, and people, in use by 1829)

white root (South Carolina)

wild-laurel

yellow-wood [yellowwood] (named because the plants were in use to make yellow dyes before 1767; one of many trees called “yellow-wood”)

In 1760, Nicolaus von Jacquin published his book *Enumeratio Systematica Plantarum* (Enumeration of Plant Systematics). In that volume, he described a new genus that he

called *Symplocos martinicensis* for trees he had collected in Martinique. Then, 6 years later, Linnaeus published the name *Hopea tinctoria* for

***Symplocos tinctoria*.** a. Flowering branch, b. Flower showing branched filaments, c. Flower showing calyx and bud scales, d. Fruiting branch, e. Drupe. Drawn by Vivian Frazier. From Correll and Correll 1972.

plants collected by Alexander Garden, a physician living in Charleston, South Carolina.

Subsequently, French magistrate Charles Louis L'Héritier de Brutelle realized that the trees discussed by Linnaeus were the same genus as those reported by Jacquin from Martinique. Therefore, in 1791, L'Héritier created the modern name *S. tinctoria*. There are now 250 species in the genus (Mabberley 1997). The family, Symplocaceae, which comprises this single genus, was created in 1820 by René Louiche Desfontaines (1750–1833), a French professor at the *Jardin des Plant es*, Paris.

*Symplocos tinctoria* is endemic to the southeastern United States where it grows from Florida to Texas and Arkansas, and north along the Coastal Plain and Blue Ridge to Delaware (Small 1933, Fernald 1950, Correll and Johnston 1970).

The first record of these trees in Florida was by William Bartram ([1791] 1958), who called them *Hopea tinctoria*. He found the plants along the St. Mary's River along the Georgia-Florida line in 1773, later on the St. Johns River above Lake Dexter, near Salt

Springs in Marion County, and near the Alachua Savanna (Paynes Prairie of today) in Alachua County (Bartram [1791] 1958, Taylor and Norman 2002).

Linnaeus knew that the plants were used for dyes, as indicated by the species name, *tinctoria*. Small (1933) and others said that a yellow dye may be obtained from leaves and bark. Hocking (1997) said that the fruits also yield the dye.

The wood is close grained, and the heartwood is brown or red, but light and soft (Small 1933). Although never a commercially viable product, the wood has been used in turnery (Mabberley 1997). The sweet leaves are eaten by wildlife, cattle, and horses (Small 1933, Correll and Johnston 1970). Morton (1974) also found that woodsmen and campers chewed the leaves to relieve thirst.

The Choctaw used the roots to treat fever (Taylor 1940). Subsequently, settlers and blacks learned to use the plants. Standley (1920–1926) said that the root was used as a stomachic, to treat kidney ailments, and for syphilis and scrofula. Morton (1974) found people in the Low Country of South Carolina still using the roots for a “tea,” which was drunk with sugar as a beverage during meals. This drink was so popular that workers at the Brookgreen Gardens had to be stopped from pulling up seedlings.

Hocking (1997) noted that the roots have been used as a tonic, stomachic, and digestive. He also noted that the plant has been used to treat asthma among the Gullah.

The genus contains tannins, ellagic and gallic acids, and some produce methyl salicylate or indole alkaloids of the carboline group (Cronquist 1981). Several of those chemicals are bioactive, and would produce some of the results desired in medical application. Not surprisingly, no chemical studies seem to have been done on the American species, but there are several on the Asian plants. In those, arabinogalactan, lignan glycosides, phenolic glycosides, triterpenoids, and sweetening agents have been found (Hussain et al. 1990, Ahmad et al. 2003, Li et al. 2003). Others found anti-AIDS agents, antimicrobial activity, antiplasmodial impacts, analgesic activity, and support for historical use against gastrointestinal problems and fevers (Inouye et al. 1973, Tiwari and Tripathi 1976, Grosvenor et al. 1995, Sampson et al. 2000, Horgen et al. 2001, Ishida et al. 2001, Khan et al. 2001).

# T

## *Taxodium*

(L.C.M.Richard named this from *taxus*, the classical Greek name of a European conifer, and *eidos*, resembling)

***Taxodium distichum*.** From Sargent  
1905.

***Taxodium distichum*** (two-ranked, like a feather)

*ahuehuete* (from *ahuehuatl*, Náhuatl, Mexico)

*amerikanische Zypresse* [*amerikansk Cypress*] (German, North America)

*asawî* [*ashuit*] (Mikasuki); *vcenvho* [*acinahâ, acinaho, acheda, atcheda, atcheanahoe, ashinahoo, uecheanatho, vcénvhó, vncénvhó*] (Creek, Muskogee; see also *Juniperus*); *a'tsina'* [*a-tsi-na, a-tsi:-n'*] (Cherokee; loan-word from Muskogee); *waksiná* (maybe akin to Chitimacha *ho* *ʔaksus naʔa*, they are cypresses, Koasati)

[common] bald [pond] cypress [baldcypress, common-baldcypress] (USA); *calvo* (bald, Spanish, USA); *ciprés* [*cipresso*] *calvo* [*americano, de pantano, del sud*] ([American, swamp, southern] bald cypress, Spanish, Chiapas, USA); *cypres chauve* (bald cypress, French, USA); *taxodier chauve* (bald cypress, French, USA)

*boscoyo à cypres* (cypress knee, Houma, Louisiana)

*ciprés de Montezuma* (in the Gardens of Chapultepec, Mexico valley, was an old tree in the 1500s; estimated at 700 years old)

*cipresso delle paludi* (swamp cypress, Italian, USA)

*cypres de la Louisiane* [*cypres de Louisiane*] (Louisiana cypress, French, USA) [black, buck, cow, deciduous, Gulf, Gulf red, knee,

Louisiana black, Louisiana, Louisiana red, pond, red, river, southern, swamp, tidewater red, white, yellow] cypress (derived from Latin *cyparissus*, Greek *kyparissos*, the ancient name of an evergreen in the Mediterranean, now the genus *Cupressus*, USA)

*gagiñorí* (Guarijio, Sonora)

*moeras-cypres* [*moerascypres*] (USA)

pecky cypress (from “peck” in the sense of “an impression or hole made by pecking,” in English by 1591; the term was applied specifically to *Taxodium* with pockets of decay by 1848, USA)

*pentamu* [*pentamón*] (Tarascan, Tamaulipas)

pine barren cypress (for *T. ascendens*, Williams [1837] 1962)

pond *cypres* (mixture of English and French, USA)

*sabino* (from the Latin for a *Juniperus*, which see, Sonora to Oaxaca)

*satine faux* (false satin, French, USA)

*shankolo* [*shamgo'lo*] (Choctaw); *siwaakola* (Alabama); *shankolo itibbi* (cypress knee; *itibbi*, battle, Choctaw); *siwaakola impisi* (cypress knee; *siwaakola*, cypress, *im*, its, *pisi*, breast, Alabama)

sump-cypress (swamp cypress, USA); *Sumpftaxodie* (swamp taxodium, German, USA), *Sumpfzypresse* [*Sumpcypress*] (swamp cypress, German, USA); *virginische Sumpfedar* (Virginia swamp-cedar, German, USA)

*tnuyucu* or *yucu-ndatura* (Mixtec, Oaxaca)

*txut* (Atakapa)

*yaga-chichicino* or *yaga-guichi xiña* (*yaga*, tree, *guichi*, cedar, *xiña* from *xiña*, red, Zapotec, Oaxaca)

Depending on the taxonomy followed, the North American endemic genus *Taxodium* contains one, two, or three species. The latest view is that there is a single species (Watson 1993). Probably the first record of these trees was in the account of Hernando Cortés weeping under one in the village of Popatela close to Mexico City. Supposedly, Cortés wept under the *Arbol de la Noche Triste* (tree of the sad night) on the night of 1 July 1520 after a disastrous battle (Stanley 1920–1926, Felger and Johnson 2001). The *Arbol de la Noche Triste* and the *Arbol del Tule* are now more than 500 years old. Although it appears to be several trunks fused, the *Arbol del Tule* at Santa Maria del Tule, Oaxaca, is considered to have the largest trunk circumference of any tree in the world (Dorado et al. 1996).

The trees are famous for providing timber, medicines, and resins, although there are other uses. Gilliland (1975) found that the Glades people used cypress wood before Columbus. From the Marco Island site dated at about A.D. 1300, trays, cups, bowls, and tubs were identified.

In historic times, Seminole relatives the Choctaw used the bark to make cords (Bushnell, 1909). The Houma used scrapings from the *boscoyo à cypres* (cypress knee) and mixed them with whiskey to purify the blood (Speck 1941). Houma also used the inner bark to cure jaundice. Sturtevant (1955) found the Miccosukee using cypress to build houses, canoes, dance posts, coffin logs, medicine bowls, spoons, food paddles, in tanning skins, to make arrowheads, drums, ox yokes and bows, heddles, mortars and

pestles, and ball poles, spoon ball sticks, and dolls. They still use it. Their use likely reflects to a large extent that of their predecessors, the Glades people.

Standley (1920–1926) noted that Mexicans use the wood for planks, furniture, and general construction. In pre-Conquest times, the tree provided an acrid resin used to treat wounds, ulcers, skin diseases, toothache, and gout. The bark is used as an emmenagogue and diuretic, and the leaves relieve itch. Chips of wood are buried and fired, and yield a kind of pitch that is used to treat bronchitis and other chest problems. Martínez (1969) recorded the same basic uses in practice as in earlier records. Many of the same applications were made of the U.S. variations (Hocking 1997).

### *Taxus*

(From Greek *taxos*, the yew-tree)

*barlind* (conifer-linden, Norwegian)

*tasso* (from Latin *taxus*, Italian); *teixo* (Portuguese); *tejo* (Spanish)

yew (from Old English *īw*, *éow*, dating from A.D. 725; akin to Old Saxon *ihm* Middle Dutch *iwe*, and Old Norse *yr*, bow); *eo* (Old Irish); *Eibe* (German); *hivin* (Cornish); *id* (Swedish); *if* (Quebec, France); *iff* [*ijf*, *ipe*] (Dutch); *iogh* (the ninth letter of the Gaelic alphabet); *iubhar* (Gaelic); *iuir* (Irish); *iva* (Spanish); *iven* (Breton); *ivos* (Old Celtic); *jevà* (Lithuanian); *ur* [*uir*] (Gaelic); *ywen* (Welsh); the French and Spanish may be derived from from Latin *ivus*, or all may be related to that source

### *Taxus floridana* (of Florida)

Florida yew

Florida's endangered yew is confined to the margins of the Apalachicola River in Gadsden and Liberty Counties in the Panhandle (Coile 2000). The population of this and the related *Torreya taxifolia* are relicts of the last Pleistocene glaciation, and both are narrow endemics to that region. Like all *Taxus*, the Florida species is poisonous and would have been used by people living in its vicinity.

The yews are plants of ancient association with people in the Northern Hemisphere (de Cleene and Lejeune 2002). The similarity of names in European languages for the plants is one measure of its antiquity. These trees figure in classical Greek legends, and many of the views from that time persist in modern beliefs.

European yew (*Taxus baccata*) was dedicated to the Erinyes or Furies, goddesses of vengeance (Baumann 1993). These Furies punished human evil-doers in various ways, but one of their favorites was with poison from the yew. The needles contain an alkaloid so poisonous that 500 g is enough to kill a horse. Artemis, goddess of the chase, was commanded by her mother Leto to kill the children of Niobe. Those children had insulted Leto and she wanted revenge, so Artemis tipped her arrows with poison from yew. Artemis herself was worshiped in a temple that Theophrastus placed in a luxuriant forest of yews on the Artemision promontory of Arcadia.

Roman author Pliny (A.D. 23–79) wrote of the yew that the “berries are poisonous. Sextius states that the ...Arcadian variety has such an instantaneous effect that it is fatal to sleep under it or eat one’s food beneath it. Some authorities claim that this is the reason why poisons were called *taxic* or *toxic* meaning ‘that in which arrows are dipped.’” Editor and translator Healy (1991) put in a footnote regarding Pliny’s text that *toxon* is Greek for bow, while *taxus* is Latin for yew. He could have added that “yew” meant “bow.”

There is a remaining ambivalence toward the yew tree because of its history in Europe. The beneficent aspect of the yew lay in its wood, and it was highly prized in Europe because it was the best for making bows. Legend has it that Robin Hood’s longbow was made of yew. Some also consider yew branches to make the best arrows (Vickery 1995).

Yew plants are associated with supernatural powers, and therefore considered capable of diverting evil. The same ideas were held by the Druids and other Celtic people, and the yew was more sacred to the Druids of Scotland than the oak (Dwelly 1933). Yews were planted by the Druids near their temples, and the Christians continued that practice. The shift may have been as simple as using an old Druid temple for Christian services and inheriting the trees with it, but it was probably more complicated than that.

Churches, whether Druidic or Christian, always had hallowed ground surrounding them. That holy land was used by communities as their graveyard. Because the yew has red heartwood and white sapwood, Christian leaders promoted the belief that those were the colors of the blood and body of Christ. Perhaps Druids used the same symbolism for their deities. Either way, the yew came to be considered a deterrent to evil spirits. Many cultures still plant a yew in a graveyard, believing it will disperse malevolent spirits. Except in cultures that have lost the old beliefs, yews are rarely planted near houses.

In Ireland, where palms occur only in greenhouses, the yew is a substitute on Palm Sunday—known as *Domhnach an iuir* (Yew Sunday) (Vickery 1995). The branches may be worn afterward and pieces are often placed in people’s homes to bring good luck. Similarly, the yew substitutes for the ash (*Fraxinus*) on Ash Wednesday ceremonies. After the ceremony, some people put the branch in the cow byre, while others put it beside a religious picture in their kitchen.

Indigenous people in the Americas also knew and used *Taxus*. There are three species native to North America: *T. brevifolia* in the northwest, *T. canadensis* in the northeast, and *T. floridana* in Florida. Records exist that various tribes used the two most widespread species, *T. brevifolia* and *T. canadensis*, and adopted the European *T. baccata* and Japanese *T. cuspidata* into their pharmacopoeias (Moerman 1998).

Both native species have been used in a variety of medicines. Eastern tribes used *T. canadensis* in minute amounts to make tea to treat rheumatism, bowel ailments, fevers, colds, scurvy, to expel afterbirth, dispel clots, and as a diuretic (Foster and Duke 1990, Moerman 1998). The plant is so poisonous with the alkaloid taxine that as few as 50 needles (“leaves”) have resulted in death (Foster and Duke 1990). Duke et al. (2002) consider all three species (*T. baccata*, *T. brevifolia*, *T. canadensis*) unsuitable for medicinal use.

*Taxus* is not only a plant, it is an animal. Since 1535, it has been the English derivation of Medieval Latin for the badger (OED 1971). The scientific name of the European badger is *Taxidea taxus*. How two such different organisms came to be called by the

same name is a mystery. However, analysis of the animal's name reveals an unexpected connection. *Taxidea* is composed of Greek *taxos*, the yew, and the suffix *ide*, pertaining to trees. Thus, the badger is an animal that hides in the forests of yew.

### *Tephrosia*

(From Greek *tephros*, ash-colored or hoary, a reference to the gray pubescence of the leaves of many species)

***Tephrosia virginiana*.** From Britton and Brown 1897.

***Tephrosia florida*** (of Florida)

*Aschenwicke* (ash-colored vetch, German)

Florida hoary-pea [hoarypea]

***Tephrosia hispidula*** (with short, straight hairs) sprawling hoary pea

***Tephrosia virginiana*** (of Virginia)

*a:tatini:li iyyaksi* (*a:tatini:li*, bad man's [devil's], *iyyaksi*, claw, Koasati)

cat-gut [catgut] (applied by 1599 to violin strings, although no such use has been recorded beyond the name; Britton and Brown were using the plant name in the Americas by 1896)

*distai'yí* (the roots are tough, Cherokee)

goat's-rue (wild rue, a comparison to *Ruta graveolens*, perhaps because of the compound leaves; Britton and Brown were using the name in the Americas by 1896)

*haashshachi' isholosh talakchi'* (*haashshachi'*, devil, *im*, his, *sholosh*, shoe, *talakchi'*, tied up, Chickasaw); *siitan isholosh takachi'* (*siitan*, Satan, *im*, his, *isholosh*, shoe, *takachi'*, tied up, Chickasaw); devil's shoestring (the long poisonous roots)

*hó:fi:pí* [*hó:ri:pí*]/*[hó:ri:pí]* (Mikasuki); *hvloneske* [*aloniskâ:*, *aloniski*, *haloniski*, *hvnleske*, *vlonéske*] (Creek); *ṭako*[*rako*] *niski* (by Howard 1984, Muskogee); *imallun̄sak* [*issimallun̄sak*, *imisin̄lusak*] (*isi*, deer, *in̄*, its, *allun̄sak*, baby, Choctaw)

*loksimpolona* (*loksi*, turtle, *im*, its, *polona*, string, Chickasaw)

rabbit's-pea (i.e., wild pea)

*suckehihaw* [*soo-ke-he-aw*] (young turkey's food; *çii-ka*, turkey, *i-ha* 'mouth, Osage); turkey pea (translation of Osage name use by Hunter [1823] 1973)

Virginia tephrosia (a book name)

*ya-mbara?* (bad-man's [devil's] string, Catawba)

*Tephrosia* is a tropical genus with about 400 species (Mabberley 1997). The most famous species in the eastern United States is also the first that became known in Europe. Leonard Plukenet described these in 1696 as a *Cicer*. He mentioned them in another book published in 1700, but then changed his mind and called them *Orobus*. Finally, Linnaeus and Gronovius examined John Clayton's specimens and decided that they should be called *Clitoria foliis pinnatis* (butterfly-pea with pinnate leaves). Linnaeus realized that too was incorrect, and called the herbs *Cracca virginiana* in 1753. At the time *Cracca* was interpreted broadly, and included species now known to belong elsewhere. It was finally 1807 when C.H. Persoon described the genus *Tephrosia* to accommodate this and related species. The other two Florida species were first reported by André Michaux in 1803 under another genus.

Goat's rue or devil's shoestring (*T. virginiana*) became the most famous of these plants not only because of its early discovery and popularity among indigenous tribes, but also because chemists learned it contained rotenone. The species contains rotenoids and flavonoids, including rotenone, dehydrorotenone, tephrosin, and deguelin (Kinderscher 1992). Rotenone has shown anticancer activity, but is also described as carcinogenic. Duguelin, rotenone, and tephrosin can cause paralysis and death but are not as toxic to humans as they are to fish and insects. Roots and leaves are the parts used in medicines because the wood and seeds are toxic (Foster and Duke 1990, Kinderscher 1992).

Long before chemical studies were made, south-eastern people used the plants to gather fish. The Miccosukee used it as fish poison even though it does not grow on the Big Cypress Seminole Reservation in southern Florida (Sturtevant 1955). The Miccosukee use was a tradition passed on from their ancestors and their Choctaw and Yuchi allies who all used the plants farther north (Byington et al. 1915, Sturtevant 1955). The retained name among the Oklahoma and Florida Seminoles indicates the antiquity and extent of use to obtain fish.

Most of the extant records for this species are for medicinal uses, as are all records for the other two species. The second most important application of *T. virginiana* was to eliminate intestinal worms. At least the Cherokee, Osage, Kansas, Koasati, and Pawnee used it for that purpose (Hunter [1823] 1973, Krochmal 1968, Hamel and Chiltoskey 1975, Kimball 1994). Settlers also adopted the remedy. Porcher (1863) wrote, "The roots were used by Indians, and are now employed in popular practice as a vermifuge; a decoction is said to act as powerfully and as efficiently as the pink root (*Spigelia*)" Millspaugh (1892) agreed.

The Creeks also mixed devil's shoestring with sassafras to treat bladder problems and coughs, including tuberculosis (Swanton 1928a). Creek women suffering from irregular periods bathed in liquid made from *Stillingia sylvatica* and *T. virginica* (Swanton 1928a). The same mixture was used to treat male impotence. The Chickasaw used the roots to "draw poison" from a hurting chest (Howard 1985). The Choctaw used it to treat fever and malaria (Byington et al. 1915). The Oklahoma Seminoles made a tea that is drunk as treatment for general malaise (Howard 1985), and the Cherokee did the same (Mooney 1885–1886).

The Cherokee had several other uses. Women washed their hair in a root decoction to prevent it from falling out. They believed the toughness of the roots would be transferred to their hair. Cherokee ball players rubbed the decoction on their limbs to toughen them (Mooney 1885–1886). Decoctions were given to Cherokee children to make them strong (Taylor 1940, Ajilvsgi 1984). The Catawba used the leaves to treat fever and rheumatism (Moerman 1998).

A decoction of mashed *T. florida* roots were applied to sores by the Choctaw (Taylor 1940). The Koasati applied an infusion of roots to snakebites (Taylor 1940). The Choctaw chewed roots of *T. hispidula* and swallowed the juice to stop coughs; too much would loosen the bowels (Campbell 1951).

The U.S. Dispensatory of 1885 considered the plant cathartic and the roots tonic and aperient (Vogel 1970). Duke et al. (2002) indicate that *T. virginiana* has been considered allergenic, analgesic, anticancer, anthelmintic, antileukemic, carcinogenic, diaphoretic, insecticidal, laxative, piscicidal, stimulant, and tonic. In the proper dose, they consider it as safe as drinking a cup of coffee.

### *Tetrazygia*

(From Greek *tetras*, four, plus *zygon*, yoke, a reference to the four-parted flowers of *T. tetrandra*)

#### *Tetrazygia bicolor* (two-colored)

*cordobancillo* (probably based on *cordabán*, alluding to a use for tanning skins; ultimately from *Córdoba*, a city famous for leathers, Cuba)

Florida clover ash

tetrazygia (a book name)

***Tetrazygia bicolor*.** a. Branch with flowers, b. Flower, just before opening, in side view and in longitudinal section. c. Flower, just after opening, the stamens still folded. d. Open flower, from above, e. Open flower, longitudinally dissected, f. Stamen, g. Anther pore. h. Floral diagram. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

In 1768, Philip Miller named plants growing in London *Melastoma bicolor*. That genus, created by Burmann in 1737 and adopted by Linnaeus ([1753] 1957), already had seven species, including four that Linnaeus knew grew in the Americas.

As more plants were found during exploration of the world, people realized that the Caribbean plants did not fit in *Melastoma*. Finally, in 1828, the genus *Tetrazygia* was created by L.C.M. Richard and A.-P. de Candolle, based on *T. tetrandra*. Belgian researcher Célestin Alfred Cogniaux (1841–1916) moved the Florida species to *Tetrazygia* in 1891. Now the genus contains 25 species, and it is known from Florida and the West Indies (Mabberley 1997).

*Tetrazygia bicolor* is found in Florida, the Bahamas, Cuba, and Hispaniola (Small 1933, Leon and Alain 1957–1963, Correll and Correll 1982). The species has been reported from Jamaica, but Adams (1972) separated their plants out as *T. pallens*.

Jamaicans call *T. pallens* clover ash, which gave rise to the common name listed by Wunderlin (1998) for Florida plants. The other names of the Jamaican trees are ashes bush, ashes wood, and black ashes, so the name “clover ash” is not a comparison with *Fraxinus*.

Florida’s plants are restricted to small parts of Miami-Dade and Monroe Counties. There the hammocks and pinelands are disappearing because of urbanization, and the species is considered threatened (Coile 2000).

The only record of use for *T. bicolor* is from the Bahamas. There a leaf decoction has been used to reduce night sweats (Higgs 1969). Unfortunately, Higgs gave little information, and Morton (1981) found no other mention of people using the plant.

The Cuban common name *cordobán* is applied to at least eight other members of the Melastomataceae. Similarly, *cordobancillo* is used for 16 other members of the family, including the medicinal *Miconia laevigata* (Morton 1981). Since a number of *Miconia* and other genera in the family are notable hemostats, it seems likely that *Tetrazygia* is also rich in tannins. Cronquist (1981) confirmed that several members of the family contain tannins.

### *Teucrium*

(From *teukrion*, possibly for *Teucer* or *Teukros*, the founder of the town of Salamis in Cyprus)

***Teucrium canadense*.** From Britton and Brown 1898.

*darag thalmhuinn* (*darag*, oak, *thalmhuinn*, earth, Gaelic)

germander (a corrupted form of Greek *chamaedryas*, ground oak; the original is commemorated in *Teucrium chamaedryas*, USA, England); *calamandrea* (Italian); *camadréo* (Spanish); *Gamander* (German); *germandrée* (French)

***Teucrium canadense*** (of Canada)

*agrimonia* (Spanish; see also *Agrimonia*)

American germander

*kofuckv* [*kofucka*, *kofucke*, *kaput cka*] (Creek, Muskogee; also used for

*Monarda*, which see)

snake-weed (Missouri)

wild basil [sage] (USA)

To Europeans, one of the best-known germanders was *Teucrium chamaedryas*, which has been used to make a medicinal tea since antiquity. Another wellknown germander is *T. marum*, although we now call it “cat thyme” (Mabberley 1997).

The Seminoles in Oklahoma tie some of the leaves into a small sachet at the back of their neckerchief when attending the Stomp Dance (Howard 1984). They may have historically used the plant, or they may have imitated the people of the prairies and plains who used sachets of perfume in their War Dance bandoleers, or even the peyotists (Howard 1984).

A leaf tea among settlers was used to induce menstruation, urination, and sweating (Foster and Duke 1990). This species was also used like *Lycopus* for lung ailments, worms, and piles, and externally as a gargle and antiseptic dressing (Foster and Duke 1990).

***Thalassia***

(From Greek *thalassa*, *thalatta*, the sea, because these are submerged marine plants; akin to Akkadian *apsu*, sea, deep water, *sala'u*, besprinkle)

***Thalassia testudinum*** (of turtles, because the plants grow where these animals live near shore) seaweed

[Caribbean] turtle-grass

*Thalassia* was proposed as a genus by Sir Joseph Banks and Daniel Solander, but not published, and it was later formalized by C.D.E.Koenig in 1805. There is one species in the Caribbean and another in the tropical Indian and Pacific Oceans (Mabberley 1997).

The leaves are used as fertilizer, at least in paddy fields and coconut plantations (Hocking 1997, Mabberley 1997).

***Thalassia testudinum*.** a. Sterile plant (left) and pistillate plant (right), b. Staminate flower bud. c. Staminate flower, side view (left) and longitudinally dissected (right), d. Floral diagram of Staminate flower, e. Pistillate flower, side view (left) and dissected (right), f. Fruit, g. Floral diagram of pistillate flower. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

### ***Thalia***

(This is one of Linnaeus's double origin names; ostensibly he named it for Johannes Thal (1542?– 1583), a German physician at Stolberg am Harz; however, he surely did not miss the allusion to the muse *Thalia*, who presided over comedy)

***Thalia geniculata*** (with knees, meaning the jointed stems)

*agutiguepe-obi* [*agutigvepo-obi*] (first reported by Marcgraf and Piso in 1648, Brazil; according to Ferreira ca. 1978, *aguti* from *aku'ti*, the Tupí for the mammal *Dasyprocta araruta*; the *guepe* is unexplained; and *obi*, of African origin, akin to Twi *a'bia'a*; the implication is that the plant is

eaten by the mammal, and that it is used in Macumba rituals, but no further information has been found)

alligator flag (presumably because it is one of the “flags” that grows in wetlands frequented by these large saurians, Florida)

***Thalia geniculata*.** From Institute of Food and Agricultural Sciences.

*arumarana* (*aruma*, from *aru'mã*, a name for *Ischnosiphon ovatus*, another member of the Marantaceae, *rana*, false, Tupí, Brazil)

*co:kít a* [*shogita*, *shongikee*] (to suck, Creek); *soki:kí* [*çonkigi*, *sonkiiki*, *shongiskehi*] (suck it, Mikasuki)

fire-flag [fireflag] (Florida)

*glaïeul* [*glade*] (*gladiolus*, Hispaniola); *gorgeau* (gullet, but probably from *glaïeu*, Haiti)

*pámpano* (probably from Quechua *pampa*, plain, prairie, Puerto Rico)

*platanar* (of bananas, Belize); *platanillo* [*de río*] (little [river] banana, Dominican Republic, Belize, Panama)

swamp lily (Panama)

*waha* (Miskito, Nicaragua)

*zolupa* (Hispaniola)

Bauhin knew these wetland herbs from cultivation in Europe in 1623. Marggraf and Piso reported them in eastern Brazil in 1648. Hans Sloane later recorded the plant in Jamaica in 1696. Thus, the plants had been in Europe a long time when Linnaeus finally gave them their name in 1753. Now, there are seven species in tropical America. In a range like that of *Annona glabra*, these herbs also reappear in western tropical Africa (Mabberley 1997).

Although Sturtevant (1955) recorded that the Miccosukee used *soki:ki* as food, he did not elaborate. Morton (1968) and Duke (1972) note that the inner part of the boiled root is edible. Morton's (1968) description of it as looking like coral-pink shrimp inside makes it sound palatable, but she says it has a "swampy" flavor.

Bennett (1997) was told that the fresh roots are eaten and that the flowers, rhizomes, and base of the stem were edible, and used especially during wartime. Leaves were also used to cook food. Corn bread dough was mixed with meat and rendered fat, and then boiled in the leaf, like a *tamale*, but the Miccosukee call it *paluee*. Beans sometimes were added. Corn meal and fat, wrapped in leaves, were boiled in four different pots at a time, as an unspoken "offering" to the gods of the four winds.

In western Africa, the stems were used for basketwork, and the leaves were used as a packing material (Dalziel 1937). Since there were no comparable leaves in Florida before the introduction of bananas, perhaps indigenous people also wove with them. Grimé (1976) found an apparently unique application of the plants being used to neutralize poison in Jamaica in the 1790s. The Brazilians use the rhizomes as a medicine on sores and apply it as an antiseptic (central nervous system stimulant) (Mors et al. 2000).

### *Thalictrum*

(From Greek *taliktron*, a name of some plant mentioned by Dioscorides, fl. A.D. 40–80, with coriander-like leaves; Pliny, A.D. 23–79, applied Latin *thalictrum* or *thalitruum* to the meadow-rue)

***Thalictrum thalictroides*.** From Britton and Brown 1896.

*frøstjerne* (stone seed, Norwegian)

meadow-rhubarb; *rubarbio de los pobres* (poor people's rhubarb, Spanish); *ruibarba dos pobres* (poor people's rhubarb, Portuguese)

meadow-rue (in use by 1653 when Culpeper used the modifiers "meadow or wild" to distinguish between these plants and the cultivated rue, *Ruta graveolens*); *rù beag* (*rù*, rue, *beag*, little, Gaelic); *ruda cimarron [de la sierra]* (wild [mountain] rue, New Mexico); *Wiesenraute* (meadow rue, German)

*nisude-hi* (*nisude*, flute, *hi*, plant, Omaha-Ponca)

*pigamo* (from Greek *peganon*, the name of *Ruta*, Italian); *pigamon* (Quebec)

*skadiks [skariks]* (Pawnee)

*talictro* (from *Thalictrum*, Portuguese)

*wazimma* (*wazi*, pine, *mna*, to smell, Dakota)

***Thalictrum cooleyi*** (named for George Ralph Cooley, 1896–1986, a wealthy benefactor of the botany programs at the University of North Carolina, Chapel Hill, and the University of South Florida, Tampa)

Cooley's meadow-rue [meadowrue]

***Thalictrum macrostylum*** (long-styled)

piedmont meadow-rue [meadowrue]

***Thalictrum revolutum*** (leaves with the edge rolled back)

maid-of-the-mist

[purple, skunk, skunk-leaved, wax-leaf, wax-leaved, waxy, waxy-leaf]

meadow-rue [meadowrue]

***Thalictrum thalictroides*** (resembling *Thalictrum*)

[rue] anemone (Ohio)

may [star, wind] flower (Massachusetts, Ohio)

wild-potato ("I know of mountainous districts in Pennsylvania where these roots are collected and eaten under the name of 'wild potato,' "Medsger 1939 in Coffey 1993)

The history of the European common names for *Thalictrum* is bound up with those for two other plants, rue (*Ruta graveolens*) and rhubarb (*Rheum rhaonicum*, from Greek *rheon*, root, and *Rha ponticum*, the root that grew on the *Rha*, Volga River). Because of Old World uses, and because of leaves similar to rue, *Thalictrum* was compared to both. Both *Rheum* and *Thalictrum* are purgative, and *Ruta* and *Thalictrum* have been used as spices.

Rue has as common names *Raute* (German), *ruda* (Portuguese, Spanish), *rue* (French), and *ruta* (Italian). *Ruta* is based on the Greek *rhyte* and Latin *ruta*, bitterness or a bitter herb. Related words are Akkadian *ratu*, to fortify, and Hebrew *ratam*, to bind fast. Rue

was in use in English by ca. 1382. In Arabic, rue is *fegan*, which is cognate to Greek *peganon*.

Rhubarb is *rabarbaro* (Italian), *reubarba* (Portuguese), *Rhabarber* (German), *rhubarbe* (French), and *ruibarbo* (Spanish). These names were all derived from Latin *r(h)eumbarbum*, bearded root. These plants are not native to Europe. They were introduced from the Far East before 1400 when rhubarb appeared in English. For example, John Gerarde wrote in his *Herball* of 1597, “The best Rubarbe is that which is brought from China fresh and new.”

The Cherokee took an infusion of *T. thalictroides* to stop diarrhea and vomiting (Hamel and Chiltoskey 1975). They used *T. dioicum* for the same maladies. The Iroquois also used *T. dioicum* to treat sore eyes resulting from head colds, and to treat heart problems (Moerman 1998). The only other eastern species recorded as used is *T. pubescens*, which the Iroquois used in a bath to stop nosebleeds and for gallbladder problems (Moerman 1998). The Montagnais (Quebec) spice salmon with the leaves (Moerman 1998).

From the Great Plains west, Moerman (1998) documented six other species used as spices in foods, as deodorants, medicines, and toy flutes.

### *Thelypteris*

(From Greek *thelys*, female, and *pteris*, fern; used by Theophrastus, 372–287 B.C., and Dioscorides, fl. A.D. 40–80, and resurrected by Casimir C.Schmidel in 1762)

***Thelypteris kunthii*** (named for Carl S.Kunth, 1788–1850, professor of botany, Berlin) (= *T. normalis*)

fern (Bahamas)

[lady] maiden fern [palm] (apparently a comparison with maiden-hair fern, *Adiantum*, Florida, Bahamas, Belize)

southern shield-fern (Florida, Bahamas)

*taapente* (fern, Mikasuki)

*tapinthiskitilikmi* [*tapinthisçilikmi*] (delicate foliage fern, Mikasuki)

***Thelypteris palustris*** (of marshes) marsh fern

***Thelypteris kunthii*** a. Upper part of frond and rhizome, b. Two pinnules to show venation and sori. *Drawn by Jane W. Roller.* From Correll and Correll 1982.

Wunderlin (1998) included 14 species of *Thelypteris* native to Florida. Documentation of uses for only two was found, but it is likely that others were similarly applied.

Sturtevant (1955) was told that the leaves were used for “Old Paint Woman’s Sickness” (weakness of limbs and neck). The Seminoles called this malady *hamocolo:pi* (paint old woman or paint witch, Mikasuki). There is no recorded connection to this use and the plant *hamockolo:pintapinti* (paint old-woman’s fern, *Osmunda regalis*, which see).

In the Bahamas, they take leaves from the maiden fern, parch and powder them, and sprinkle the dust on dermatitis caused by poisonwood (Morton 1981). The Iroquois used the roots of *T. palustris* for “woman’s troubles” (Moerman 1998).

Hocking (1997) recorded this species under both *T. dentata* and *T. kunthii*, apparently based on Sturtevant (1955) and Morton (1981).

***Thrinax***

(Olaf Swartz used the Greek for fan, in reference to the leaves)

***Thrinax morrissii*** (named for D.Morris, assistant director of Kew Botanical Gardens, who first discovered this palm on Anguilla Island in 1890)

buffalo-top (Bahamas)

*guano de sierra* (mountain palm; *guano*, palm, Taino, Cuba)

*miraguano* (*mira* perhaps corruption of *lana*, ocean, *guano*, palm, Taino, Cuba)

*palma de cojollo* (little testicle palm, Puerto Rico); *palma de escoba* (broom palm, Puerto Rico); *palmito* (little palm, Cuba)

*pandereta* (panderer, Puerto Rico)

peaberry palm (Florida)

[brittle, broom, key, little, prickly, small-fruited] thatch [palm, thatch-palm] (Bahamas, Florida, Puerto Rico, West Indies)

*yaray* (presumably from *yara*, place, or *yerén*, fruit, Taino, Puerto Rico)

***Thrinax radiata*** (rayed)

*bayal* (*baay*, net for carrying things, but usually a name given to *Desmoncus orthacanthos*, Maya, Yucatan)

*ch'it* (simple term, Maya, Yucatan, Belize)

fan palm (Belize)

*guanillo* (little palm, from *guano*, a palm, Taino, Dominican Republic); *guano Campeche* (Campeche palm, Mexico); *guano de cost a* (coastal palm, Cuba); *guano de lana* (ocean palm; *guano*, palm, *lana*, ocean, Taino, Cuba)

*kanalxan* (*kanal*, tall, *xan*, feces, also the common name for *Sabal japa* or *S. mexicana*, Maya, Yucatan)

*kultok* (*kul*, short, *tok*, hard, resistant, Maya, Yucatan)

large-fruited thatch-palm (Bahamas)

*latanier-de-la-mer* [*latanier la mer*, *latanier lan mer*] (seaside *latania*; *latania* is an indigenous word from Mauritius for a palm there; apparently, this native plant became confused with the one from Africa, Haiti)

*miraguano de lana* (ocean palm, Taino, Cuba)

*palma cana* (cane palm, Cuba)

salt water palmetto [pimenta, pimento] (Belize)

sea thatch; [Florida] thatch palm (Florida)

***Thrinax*.** *Thrinax morrissii* (right), a. Habit, b. Complete flower on left; flower, longitudinally dissected on right; below, floral diagram, c. Twig with fruits and single fruit enlarged. Drawn by Priscilla Fawcett. From Correll and Correll 1982. Detail of flowering and fruiting branches and leaf (upper left). From Sargent 1905. *Thrinax radiata* (lower left). From Sargent 1905.

Gilliland (1975) recorded palm fiber cords and netting among the artifacts on the pre-Columbian site at Marco Island that had been used by Glades people. That particular site probably consisted of cords from *Sabal palmetto*, as that was the common palm in the region. In the Florida Keys and Caribbean, *Thrinax* was more common and the preferred species. As late as Vignoles ([1823] 1977) and Williams ([1837] 1962), people in the West Indies were still using palm fibers for ropes. As the common names suggest, the leaves of *Thrinax* were preferred for thatching where they existed. Probably, it was at least partly leaves of *Thrinax* that were used by the people on Matacumbe to make the women's shawls that Fontaneda described (see *Sabal*).

Roots and shoots are considered tonic and restorative on Hispaniola (Liogier 1974). In Yucatan, the palm has a reputation of being tonic, corroborant, vigorative, sedative, nutritive, and diuretic (Morton 1981). The palm has been used to treat tuberculosis, bronchitis, and other respiratory problems. *Thrinax* also has the reputation in Yucatan of developing the mammary glands and revitalizing the sexual organs (Morton 1981). Fruits

are sweet and edible. The fiber has been used to stuff pillows and mattresses (Standley and Record 1936).

### *Tilia*

(The classical Latin name of the tree, maybe based on Greek *ptilon*, wing, referring to the winglike bract of the flower clusters)

*Tilia americana*. From Sargent 1905.

*craobh theile* (*craobh*, tree, *theile*, lime or linden, Gaelic); *theile* [*teile*] (Gaelic); *tiglio* (Italian); *tilia* (Portuguese); *tilleul* (French); *tilo* (Spanish) *lenda* (Old Teutonic; cognate with Greek *elate*, translated “silver tree” by the OED 1971, but *elate* is usually applied to fir or spruce); *lind* (Danish, Norwegian, Swedish); *linde* (Dutch); *Linde* (German)

#### *Tilia americana* (of America)

[American, Carolina, Florida, Kendall, white, yellow] basswood (“bass” is a corruption by 1691 of “bast,” fibers from the inner bark of trees; used with “wood” by 1824)

bast-tree (“bast” refers to fibers from the inner bark of trees, used in English since about A.D. 800; originally used uniquely for *Tilia*, but later applied to other plants with useful bark)

*batahkó* (Koasati); *panashuk* [*pishannuk*] (Choctaw); *ittobaksa* (*itto*, tree, *baksa*, thread, twine, Alabama; cf. also *Prunus*)

bee-tree

blacklime-tree

*bois blanc* (white tree, Quebec)

*chesawk* (perhaps this Virginia Powhatan name for the “rind of a tree like hemp” belongs here; recorded by Strachey in [1612] 1953)

daddy [monkey] nuts (an allusion to the fruits?)

*hinde-hi* (*hi*, plant, Omaha-Ponca); *hin'-dse* [*hin'-dse xtsi hi*] (Osage);

*hinshke* (Winnebago); *hintá-chan* (*chan*, wood, Dakota)

*i:-de-ha* (Cherokee)

*ittobitiima* (*itto*, tree, *bitiima*, stink, Alabama)

*lennikbi* (basswood forest, Delaware)

[American, tree, limetree] lime ("Lime" as applied to *Tilia* is apparently derived from *lind*. From about A.D. 700, "lime" meant a glue put on limbs to catch birds; shortened from "birdlime." In the 1600s, "lime" was applied to the fruits of *Citrus aurantiifolia*, and about the same time to *Tilia*. The spelling "lime" came into English from distinct sources. For the glue, it came from Latin *limus*, mud, through Old Teutonic *limo*. The name of the fruit came from Arabic *limah*.)

linden [lin-tree, southern lind, white lind] (from Old English *lind* or *linde*, used since about A.D. 700; also rendered *linn* in English and Swedish) *ohòchsera* (Onondaga) spoonwood

*tilleul d'Amerique* (America linden, Quebec); *tilleul*

*noir* (black linden, Quebec)

*vhahwv* [*uhawhu*] (Creek; according to OED 1971 the word meant *Tilia* or *Ulmus*; however, Martin and Mauldin 2000 equate the word with walnut, *Juglans*)

whistlewood (leaves used to make a whistling sound by holding them between the hands and blowing on the margin, Vickery 1995)

whitewood

wickiup (in English by 1852 as "wickiup." First recorded in [1612] 1953 by Strachey, who wrote *weihkippeis* for "hemp." Siebert 1975 has associated this with *wikepi*, bast or inner bark of linden or leatherwood. Derived from Algonquian languages; akin to Fox *wikiyap*, Potawatomi *wígobi'míc* (string tree), Ojibwa *wigub'imij* [*wigkub'imim*], Menomini *wikiop*, Cree *mekewap*, and Montagnais *mitshiuap*. Since the word means a dwelling, the association must be because the fibers were used to build the framework.)

The linden is eternally linked with Carolus Linnaeus (1707–1778), the egocentric genius who forever changed the way scientific names were written. At his home in Uppsala, Sweden, where he was professor at the university, he maintained a row of linden trees to emphasize his name.

It was in the poor Swedish town of Råshult that Carl [later Latinized to Carolus] was born to Christina and Nils Ingemarsson Linnaeus. Nils, a minister, as had been his father-in-law in the town, adopted the name "Linnaeus" during his years as a theological student. Tippo and Stern (1977) wrote that the name "was chosen from that of the linden tree...which grew in the farmland of Nils' father." If Nils had not adopted the name, the "Prince of Botany" would have been known as Carl Ingemarsson. Of himself, Linnaeus once wrote, "*Potest e casa vir magnus exire*" (A great man can come forth from a cabin).

European common names for these trees are split between Germanic and Romance languages, with the former based on *lind* and the latter from *tilia*. Because of their utility in Europe for producing strong inner bark fibers, they were also known as the wood that produced "bast" or "bass." That later became "basswood."

When Europeans arrived in the New World, they found a new type of linden. Both Leonard Plukenet in 1696 and Jan Gronovius between 1739 and 1743 listed and discussed the New World species with phrase names. However, it was Linnaeus who

gave it the binomial *Tilia americana*. Most of what Linnaeus knew about the American species was from his former student Peter Kalm.

In the village of Raccoon, New Jersey, on 17 April 1749, Kalm ([1753–1761] 1972) compared the New World tree to the one he knew in Sweden. Of the strength and toughness of *Tilia*, he wrote: “The *English* and the *Dutch* in many parts of *North America*, and the *French* in *Canada*, employ this bark in all cases where we make use of the *Lime-tree* bark in *Europe*. The tree itself is very tough, and you cannot easily separate its branches without the help of a knife: some people employ the twigs for rods.”

Kalm probably did not mention the European medicinal uses because he expected his readers to be familiar with them. Tea made from the flowers is a “classical digestive end to a continental meal, and a treatment of insomnia, nervous tension, and overwrought children” (Bremness 1994). The tea also induces sweating, which helps in colds, headaches, flu, arteriosclerosis, and may lower blood pressure (Foster and Duke 1990). Some also consider the water a skin tonic and use it in bath preparations to soothe rheumatic aches (Duke et al. 2002).

Indigenous Americans also used the tree for fiber, medicine, and as food. Basswood fibers are known from both Hopewellian and rock-shelter sites in prehistoric context. Gilmore (1931) found the bast fibers used in twine and cordage among the Ozark Bluff-Dwellers of Arkansas. Jones (1936) identified *Tilia* at the Menifee County, Kentucky, site. Whitford (1941) noted linden fiber mixed with other kinds in fabric from both Ohio Hopewellian sites and rock-shelter areas.

Among historic people, Whitford (1941) examined Delaware wampum, Menomini, Sauk and Fox, Potawatomi, and Winnebago bags, and an Iroquois burden strap made from *Tilia*. He said that it was the most commonly and widely used of fiber sources among Eastern tribes, and he only lacked material of it from the “extreme south” (i.e., to him, Kentucky, Tennessee, and Louisiana).

Other people recorded *Tilia* bark use among historic Algonquin, Cherokee, Lakota, Malecite, Menomini, Meskwaki, Ojibwa, Omaha, Pawnee, Ponca, and Potawatomi (Gilmore 1919, Smith 1933, King 1984, Moerman 1998). These people used the bark to make bags, baskets, belts, fishnets, houses (*wickiyup*), mats, netting in snowshoes, rope, sewing thread, shoes, and twine. They even used the thread for sewing up wounds (Vogel 1970).

Those same tribes used wood from the linden to make dugout canoes and lumber, but surely many more utilitarian items. Although not mentioned by Moerman (1998), the basswood was also the preferred tree for the carved masks used by the Iroquois Society of Faces (usually called False-Face Society) (Trigger 1978). One of the early records of that was given by John Bartram during his visit to the Onondaga in 1743 (Berkeley and Berkeley 1982). He wrote: “We were entertained by a comical fellow, disguised in as odd a dress as Indian folly could invent. He had on a clumsy visard of wood colour’d black, with a nose 4 or 5 inches long, a grinning mouth set awry, furnished with long teeth, round the eyes circles of bright brass, surrounded by a larger circle of white paint; from his forehead hung long tresses of buffaloes hair, and from the catch part of his head ropes made of plated husks of Indian corn.” Bartram did not understand that entertainment was not the purpose of the display. Use of the mask was meant to dispel evil (Billard 1974, Trigger 1978). The seriousness of the event should have been conveyed to Bartram by Schikellamy, his Delaware guide, when he warned, “Lie still, John” at the beginning of

the event. Before that moment, Bartram had never heard Schikellamy “speak so much plain English before.”

The wood has been used for appliances, blinds, boxes and crates, carvings (e.g., decoys), caskets, casks, cheap furniture, cooperage, excelsior, fiber products, fixtures, furniture stock, handles, lumber, millwork, mobile homes, novelties, panels, paper pulp, plywood, shade rollers, shades, signs, sporting goods, toys, veneers, and woodenware (Vines 1977). The USDA technical sheet on *T. americana* indicates that it “works easily with tools, making it a premier carving wood. It is poor in holding nails and in bending, but moderate in gluing and good for holding paint or printing inks.”

Only two records of use for food have been found, both among the Ojibwa. These people historically ate the young buds or cooked them as greens (Moerman 1998); they also used the sweet sap (Yanovsky 1936). Numerous people used linden as medicine. Among the tribes recorded are the Algonquin, Cherokee, Iroquois, Malecite, Meskwaki, and Micmac (Vogel 1970, Moerman 1998). These people used the inner bark in a tea to treat burns and scalds, dysentery, eye problems, heartburn, intestinal worms, lung ailments, and weak stomach. They also made a poultice to draw out boils and help heal broken bones.

Inflorescences and flowers of *Tilia* contain polysaccharides (Yakovlev 1985), kaempferol, and quercetin (Karakaya and El 1999). Water extracts were antioxidant in laboratory studies (Yildirim et al. 2000). Duke et al. (2002) noted that ethanolic bark extracts were effective against *Candida*, *Escherichia*, and *Staphylococcus*. Although no chemicals were listed by Foster and Duke (1990) or by Duke et al. (2002), they issue the warning that frequent consumption of flower tea may cause heart damage.

### *Tillandsia*

(Linnaeus commemorated Swedish physician Elias Erici Tillands, 1640–1693, professor at Abo; according to legend, Tillands was so frightened of water that he would walk several miles around a lake rather than take a boat a few hundred feet across)

***Tillandsia.*** *Tillandsia fasciculata* (left), with *Tillandsia usneoides* hanging from left side. *Tillandsia utriculata* (right), with *Tillandsia recurvata* as inset on left. All drawn by P.N.Honychurch.

***Tillandsia fasciculata*** (drawn into a bundle)

*ashome chobee* [asōmco:bî] (*ashome*, Spanish moss, *chobee*, big, Mikasuki); *assonfakko* [assonnrakko, *ashonfaku*] (*asónwa*, Spanish moss, *fakko*, big, Creek)

*curujey de lámpara* (lamp *curujey*, Spanish and Taino, Cuba)  
dog-drink-water (Bahamas)

***Tillandsia recurvata*** (curved backward, referring to the leaves)

*agave de palo* (agave on trees)  
ball-moss [ballmoss] (Florida)  
*barba di cadushi* [kadoesji] (*cadushi*'s beard, Dutch Antilles)  
*curujey* (Taino name of the plant, Cuba)  
*gallitos* (little roosters)  
*guixi guii lace* [guijxi guij lace] (*guixi*, herb, *guii*, medicine, *lace*, thin, Zapotec, Oaxaca)  
*heno* (hay, Spanish)  
*huíribis cu'u* (curve-billed thrasher's nest; *huíribis* is the name of the curve-billed thrasher, *Toxostoma curvirostre*, Mayo, Sonora)  
*man di palu* (tree *mari*, Dutch Antilles)

*mescalito* (little mescal or *Agave*, Sonora); *mescalito de huithlcochi* (little mescal or *Agave* of the curve-billed thrasher, *Toxostoma curvirostre*, Sonora)

*nido de gundulén* [*gungulén*] (*gundulén*'s nest, Puerto Rico)

old man's beard (Jamaica); old man's hand (Virgin Islands)

*pachtle* [*paschtle*, *paixtli*, *pastel de mesquite*] (*pa:xtli*, moss, Náhuatl, San Luis Potosí)

thread-leaved wild pine [three-leaved wild pine] (Bahamas)

*tiña*

*uchapoli* (Guarijío, Sonora)

***Tillandsia usneoides*** (resembling the lichen genus, *Usnea*)

*asō:mī* [*ashome*] (Mikasuki); *asónwa* [*ashunwa*, *assúnwv*] (Creek, Muskogee); *somo* (Alabama); *hassolwá* (Koasati); *iti shumo* (*iti*, tree, *shumo*, maybe "moss" as cognate with Creek *asónwa*, Choctaw)

*ayan*' *nanhi* (probably from *ayan*', tree, *nahin*', hair, Biloxi)

*barba de palo* (tree beard, Venezuela); *barba de viejo* (old man's beard, Costa Rica); *barba español* (Spanish beard, Cuba); old man's beard (recorded for *Tillandsia usneoides* by Patrick Brown for Jamaican plants in 1756; later applied to a number of plants including *Clematis*, *Saxifraga*, and *Chionanthus*, Bahamas, Jamaica, Cayman Islands)

*guajaca* (probably Taino, resembles *Guajataca*, a Puerto Rican village, Cuba)

*hichikoni* (Guarijío)

*ichokhiska hatka* (*ichokhiska*, beard, *hatka*, white, Alabama)

[crape, Florida, long, Spanish] moss (southeast USA, Bahamas);

*mousse* (moss, French, Houma, Louisiana); *musgo* (moss, Peru); *pastle* [*paixtli*] (*pa:xtli*, moss, Náhuatl, Veracruz)

*pipisqui* (Mayo)

*salvaje* (wild, Peru)

*tcinasho'hi* (Ofo)

wool-crape (southeastern USA)

***Tillandsia utriculata*** (inflated or bag shaped in allusion to the leaf sheaths)

*asōmco: bī* (*ashome*, Spanish moss, *chobee*, big, Mikasuki); *assontakko* [*assonrakkō*] (*asónwa*, Spanish moss, *takko*, big, Creek)

[giant, swollen] wild pine ("pine" is abbreviation of "pineapple," Bahamas, Florida, Virgin Islands)

Hogan (1978) found pollen of *Tillandsia* in the Glades site at Fort Center on Lake Okeechobee. Since the flowers are pollinated by animals, the people must have been using them for something. Most have presumed they used *Tillandsia* for medicine, but it may not have been that simple. Whitford (1943) reported that "in the southern regions, the natives gathered the abundant Spanish moss from the trees." They then wove the vascular bundles into what he called "blankets." He had found the blankets among

remains of the Koasati “and the people who built certain mounds in Florida used [Spanish moss] frequently” (Whitford 1941). Kimball (1994) recorded that moss is still used among the Koasati, where it is spun into strings, mattresses, and used in weaving. He quoted from one of his informants, “They looked for black Spanish moss in the forest, and when they brought it back they hung it up, scrubbed it with itself, and when they finished scrubbing it and finished lengthening it, they spun it.” They even have the word *statihká:cin*, which is a heddle for weaving Spanish moss.

Bennett (1997) was told that the moss had been used as a lid for cooking pots. He was also told that the fibers had been used to weave skirts, especially after wars when cloth was not available, and that it made an emergency blanket. The Chitimacha of the southern side of the Mississippi Delta in Louisiana made cords of the fibers and mixed the stems with clay to plaster their wattle-and-daub houses (Bushnell 1917). A woman who may have been Chitimacha said that her people also used Spanish moss to make cords (Bushnell 1922). The technique she described was the same as the one Bushnell (1917) found earlier among that tribe. When Sturtevant (1955) worked with them, the Seminoles were using Spanish moss in tanning and to skim off the scum from the surface of cooking liquid.

The Houma used *T. usneoides* in a tea to relieve chills and fever (Speck 1941). The Houma also twisted the fibers into cords, which were used, among other purposes, to make mats for the floors of their homes (Read 1931).

Large water-tank bromeliads such as *T. fasciculata* and *T. utriculata* were used by the Seminoles to obtain water during the dry season (Sturtevant 1955). Modern Seminoles told Bennett (1997) that they still obtained water from the air plants.

Cubans have used mashed leaves of *T. usneoides* mixed with butter as a remedy for hemorrhoids (Roig 1945). The same use has been made of *T. recurvata* in Argentina (Morton 1981). In Curaçao, a leaf decoction of *T. recurvata* is considered an emmenagogue, a remedy for leukorrhea, and a treatment for gallbladder problems (Morton 1981). People in Veracruz treat digestive problems with *T. usneoides* (Vásquez and Jácome 1997). Costa Ricans consider the leaves caustic and vesicant, but they use the fibers for strings and ropes (Pittier 1957). The fiber is called *cabellos de ángel* (angel hair). In Venezuela, the fiber was used to make sacks (Pittier 1926).

### *Torreya*

(Named for North American John Torrey, 1796–1873, physician and professor of chemistry, first at West Point and then at Columbia University in New York)

***Torreya taxifolia*** (with leaves like *Taxus*) fetid yew (yew with an offensive odor; from Latin *fetidus*)

gopher-wood [gopherwood] (from Hebrew *gopher*,

a kind of wood used to build the ark; probably *Cupressus sempervirens* or a species of *Acacia*; applied to American trees by the 1850s)

*Nusseibe* (nut yew, German)

savin [sacin] (a comparison with the European *Juniperus sabina*, based on Latin *sabina*)

stinking cedar [sacin]  
[Florida, yew-leaved] *torreya* [-tree]

*Torreya* is a genus of seven species. Florida has *T. taxifolia*; *T. californica* is in coastal California; and the remaining species are in eastern Asia. The genus is one of several that have a disjunction between the two regions. There are *Torreya* fossils from the mid-Jurassic, which indicates the antiquity of the gymnosperm lineage (Mabberley 1997). As ancient as these gymnosperms are, they were not discovered by the scientific community until the 1800s. Finally, the Florida plants were collected and then described by Scottish botanist George A.W. Arnott (1799–1868) in 1838. The first species described was *T. taxifolia*, and in 1854 *T. californica* was described by John Torrey.

Both U.S. species are relict populations, and the Florida plants are confined to the ravines and bluffs along the Apalachicola River valley in Florida and one adjacent county in Georgia. The Florida plants were found in three counties, but they have been extirpated from Jackson County, and they are now globally endangered by a fungus and habitat destruction (Little 1979, Coile 2000, Chafin 2001).

As several of the common names indicate, the foliage is fragrant when touched or bruised. Some considered it fetid (stinking) (Mabberley 1997).

Historically, wood from the trees was used for fencing, although the species is now so rare that is not an option (Mabberley 1997). The related species in California was used by several indigenous tribes. The Florida species were probably similarly used, but no information has been found, probably because of its rarity and comparatively late discovery. Nuts from the California species were used externally to treat headache and chills. Internally, they were made into a decoction to relieve indigestion and tuberculosis (Moerman 1998).

### ***Tournefortia*: Chiggery Grapes**

(Named for Joseph Pitton de Tournefort, physician, naturalist, and professor of medicine and botany, 1656–1708)

In the late 1600s, Charles Plumier (1646–1704) sat on the Caribbean island of Hispaniola drawing a scrambling vine with plump white fruits. This French Franciscan monk must have been impressed with the plant because he devoted a new genus to it, and named it after a friend and colleague. That friend was the eminent Joseph Pitton de Tournefort. After returning to Europe, Plumier published his drawings and descriptions of plants he had studied in a book called *Nova plantarum americanarum genera* (New Genera of

***Tournefortia*.** *Tournefortia hirsutissima* (left). Drawn by Leonardo Mourré. From Nowicke 1969.

*Tournefortia volubilis* (right), a. Branch with flowers and fruits, b. Base of leaf and petiole, c. Section of lower surface of leaf showing indument. d. Flower, side view. e. Flower, longitudinally dissected, f. Floral diagram, g. Branch of inflorescence with flowers and fruits, h. Mature fruit. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

American Plants). He called the climbers *Pittonia hirsutissima* & *ramosissima*, *baccis albis* (pubescent and branched *Pittonia* with white berries). *Pittonia* is now a synonym of *Tournefortia*. His was the first European discovery of this tropical American relative of Old World borage (*Borago officinalis*), a medicinal plant of his homeland.

We now call the American plants *T. hirsutissima*, a name given to them by the Swedish botanist Carolus Linnaeus in 1753. Linnaeus often used names proposed for plants by people who preceded him, but he sometimes changed them to suit his own idiosyncratic tastes (see Austin 1993).

Since 1753, the plants have been found throughout the Greater Antilles, on scattered islands of the Lesser Antilles, and throughout the mainland from Mexico to Peru.

*Tournefortia hirsutissima* also occurs in Florida, where it is one of the species on the Florida Department of Agriculture endangered list (Coile 2000). The species is so rare in Florida that few people know it. Those who do recognize the vine sometimes call it chiggery grapes, having imported a West Indian name. The vine is known from a half dozen or so scattered sites in Hendry, Collier, Dade, and Monroe Counties. In the Lesser Antilles it is also rare, known from Guadeloupe but not from nearby Dominica.

Even though this plant is apparently rare throughout its range, people living where it grows have a variety of names for it. To the Florida Miccosukee it is *cokashatki* (*cokasí*, grapevine, *hatki*, white). Their relatives the Creek-speaking Seminoles call it *colo: fáfā* (*colóswv*, grapevine, *fvkv*, cord) or *colo:sfakat-akko* [*colo:sfákarákko*] (*akko*, big). In Cuba, it is *nigua* (chigger), [*bejuco*] *cayaya hembra* ([*bejuco*, vine], *cayaya*, shrub, Taino, *hembra*, female, Spanish), and *bejuco cachaza* (whiskey vine). Spanish- and French-speaking people in Hispaniola call it *nigua peluda* (hairy chigger), *chique-chique* (a *chique* is a quid of tobacco, or a chigger), or *liane chiques* (chigger vine). Puerto Ricans know it as *nigua* (chigger), *mata de nigua* (chigger bush), *bejuco de nigua* (chigger vine), or chiggery grapes. Jamaicans say it is chiggernit, chigger nut, cold withe, crocus bush, or hog hook. People in Belize just say crocus, or apply their own unique names. They say it is poison fish tie tie (tie tie meaning vine) or *robo de mico* (monkey tail). Mayans in Belize say *chik*.

People in the French Antilles call it *chique en fleur* (flower for chiggers) or *herbe á melingres* (herb for a weak constitution). In various parts of Mexico it is *amapa hasta* (*amapa*=?, *hasta*, until), *mach'much'* (chew loudly vine), *ortiguilla* (little nettle), *perlas* (pearls), *tlachichinoa* (perhaps either based on *tlachichic*, referring to its bitter taste, *chiuchic* or *chichinoa*, for putting on "fire," reference to the itching, Náhuatl), *tsak ts'ohool* (red plant), *telpatli* (*patli*, medicine, Náhuatl), and *po'ko ka'hui'hui* (cool stomach, Totonac, Puebla). Nicaraguans call it *tiricia* (colloquial for *ictericia*, or jaundice) or *frutilla* (little fruit). It weeps the *lágrimas de San Pedro* (San Pedro's tears) from Veracruz to Colombia, and is *nigua* (chigger) or *nigüito* (little chigger) in Venezuela or *nigulilla* (little chigger) in Veracruz.

As several of the common names indicate, this plant is considered a remedy for chiggers (*Eutrombicula alfreddugesi*), those little red spider relatives that bite and leave itchy spots. In English, we also call them red-bugs, red mites, and harvest mites. The Creeks say *wasko*. In Latin America these tiny pests are called *tlahahuatl*, *coloradillo* (little red one), and *bicho Colorado* (red bug). Without some treatment, the itching will drive a person crazy enough to cause scratching. In a few cases, the bites may become infected. Some people even become so badly covered with bites that they go into shock. Under the best conditions the little red welts these mites cause are unpleasant. Even worse, they get in places that are not easily scratched in public without causing embarrassment. They particularly like to get in tight areas beneath underwear.

Many of the people living near chiggery grapes have learned that its mashed leaves applied to the skin alleviate this itching. Older literature says that the leaves "expel chiggers." We are now told that the animals never burrow but bite and inject us with digestive fluids that cause the itching through an allergic reaction (Nellis 1997). This application of mashed leaves has been expanded to other problems, and a leaf demulsion is used against skin diseases and ulcers on the mouth. The same preparation is used

against diarrhea and vomiting (Roig 1945, Liogier 1974, Morton 1981). *Tournefortia volubilis* is used in much the same way (Mors et al. 2000).

A look at the other common names makes it clear that people have used the plants for other purposes. Some are obvious from the name; others are not. Leaf decoctions have been used as depuratives, a preparation that “cleans” the body by causing it to excrete wastes. Leaves and roots are diuretic and have been used against venereal diseases (Standley 1920–1926, Liogier 1974). The fruits are eaten in Hispaniola and Costa Rica, and probably throughout its range (Liogier 1974).

When plants are found that have widespread usage for the same or similar maladies, it usually may be assumed that they contain bioactive chemicals. Although not a lot is known about *Tournefortia*, we do know that it contains one or more pyrrolizidine alkaloids. Several unrelated plants contain variations on this group of alkaloids, and all that have been studied are poisonous. Plants containing the compounds include *Crotalaria* and *Senna* (Fabaceae), *Amsinckia*, *Argusia*, *Borago*, *Cynoglossum*, *Heliotropium*, and *Tournefortia* (Boraginaceae), and *Senecio* (Asteraceae) (Lewis and Elvin-Lewis 1977). Many of those species known to contain pyrrolizidine alkaloids have been used as medicines.

Pyrrolizidine alkaloids may harm the human body by interfering with liver function, so ingestion of preparations using them is potentially more dangerous than the malady. Yet, people have used, and continue to use, chiggery grapes and other pyrrolizidine alkaloid-containing plants in medicines. A few people have done studies to see if groups using these preparations are suffering from higher incidences of liver problems than those not using them. The results are mixed, with some showing higher incidence of liver problems while others do not. Because the alkaloids cause liver damage in test rats in laboratories, it is thought that they cause the same or similar problems in people using the plants as medicines. That may or may not be true in all cases, because those using the plants are not extracting only the alkaloids. Instead, the people use an array of plant compounds. Could it be possible that those compounds work together to act as cures and not as liver poisons? The situation is not an either/or one, and is complicated by genetic variation in people and the plant chemicals mixed with those alkaloids in medical preparations.

Humans are actually the latest animals to discover the uses of pyrrolizidine alkaloids extracted from plants. Long before people discovered how to use the plants in medicines, insects had learned to use them in another way. Two groups of Lepidoptera are particularly well known for their use of these alkaloids—milkweed butterflies (Danaiidae, *Danaus* spp.) like the monarch, and queens, and some less well-known Ctenuchid moths (Ctenuchidae). These butterflies and moths are not particularly closely related, and independently they have both learned to extract the alkaloids from plants that contain them. However, only the male insects gather the chemicals. The males then use the plant cocktails to “intoxicate” the females of their species before they mate with them (Plisk and Saltpeter 1971, Edgar et al. 1974, Pliske 1975). Without this chemical inducement, the females will have nothing to do with the males. So, these moths and butterflies owe their continued existence to the plants that support their reproduction. I cannot help being reminded of the Ogden Nash poem, “candy is dandy, but liquor is quicker.”

***Toxicodendron: Poison Ivy***

(Named from Greek *toxikon*, poison for smearing on arrows, and *dendron*, tree)

***Toxicodendron radicans.*** Drawn by  
P.N.Honychurch.

Poison ivy and alligator fleas are two of the real “dangers” of visiting swamps. Wading into the swamp in places like Fakahatchee Strand State Preserve in southwestern Florida was always problematical. Often, we returned home with the beginnings of poison ivy (*Toxicodendron radicans*) rash on our legs. As the itchy spots were usually inside our trouser legs, oils floating on the water must have caused the problem. Tying the trouser legs around the tops of our boots always helped—with the added plus in warm weather of keeping out alligator fleas (Naucoridae). Those animals are true bugs (Hemiptera) about a half-inch long that make it a nasty habit to wait until they float up your pants legs to near the groin before biting. Their long, stiletto-like proboscis feels like a hot needle stabbing into the tender flesh of that region.

At least 50% (some say 75%) of us are susceptible to poisoning by *Toxicodendron*, relatives of cashews (*Anacardium giganteum*), pistachios (*Pistacia vera*), sumachs (*Rhus* spp.), pepper trees (*Schinus terebinthifolius*), mangos (*Mangifera indica*), and hog plums (*Spondias* spp.) (Lewis and Elvin-Lewis 1977, Nellis 1997). The active chemical, called urushiol but really a series of phenolic compounds, was discovered in the 1800s when it was called toxicodendric acid (Millspaugh 1892, Corbett and Billets 1975). This oily

material, derived from catechols, is so potent that experiments with rats show that, from a few drops on the skin, it permeates every organ within 24 hours.

*Toxicodendron radicans*, and its multiple subspecies, ranges throughout most of the United States, north to Nova Scotia and west to British Columbia and Arizona, also Mexico south to the state of Yucatan. French speakers call it *bois de chien* (dog bush, French, Canada) or *herbe à la puce* (flea herb, an allusion to the itching, Canada, Houma in Louisiana). In the United States, it is climbing sumac, cow-itch, mercury [markry], poison creeper, poison ivy, or three-leaved ivy. People often call it poison oak, especially when it is a free-standing bush and not a twiner, but according to Gillis (1971), that is another species.

The Cherokee call the plants *uluda* [*ulvda*], and the Seminoles say *hahfa:li* (Mikasuki), perhaps a simple term that is cognate with Creek *ɣfɣla* [*afala*]. However, caution is appropriate, because the Koasati called *Ipomoea* an *afalá* (Kimball 1994). The Mikasuki is also rendered *hili:háhlí*. Sturtevant's (1955) informants made the statement about the plants that *istilikwáycin* (*este*, person, *lekwicen*, gives sores, Creek) that he listed as a common name, but it is a statement, not a noun. The Alabama is different, with *baksakáńko* (*baksa*, rope, *kano-ki-o*, evil). They also call it *ittokáńko* (*itto*, tree, *kano-ki-o*, evil). The Chickasaws said *ofi' imittli'* [*ofimitti*] (*ofi'*, dog, *imittli'*, fight). The Koasati say it is *lambí pahí* (*lambí*, sting, *pahí*, grass). This is probably the *talunwa* of the Choctaw. In the Missouri River region the Omaha-Ponca call it *hthiwathe-hi* (*hthi*, sore, *wathe*, to make, *hi*, bush)—the plants that makes sores. Like people throughout its range, the Omaha knew and tried to avoid the poisonous plant (Gilmore 1919).

Some literature contends that the Glades people made an arrow poison from the leaves and stems. That seems to be an unsubstantiated extension of Caribbean use. In the Caribbean and Mexico, the plants are sometimes called *guau*. Originally, the Taino word *guau* applied to the Caribbean poisonous anacardiaceous shrub *Comocladia angulosa*. According to Bartolome Las Casas (Coll y Toste 1972): *la leche de este árbol es ponzoñosa e della e de otras cosas hacen los indios la yerba que ponen en las flechas con que matan* (the sap of this tree is poisonous and from it and other things the Indians make a mixture that they put on their arrow with which they kill). From that Caribbean application, it appears that Europeans assumed that both *Toxicodendron* and *Metopium* were used to poison arrows in Florida.

The scientific name did nothing to discourage that thinking. The genus *Toxicodendron* was created by Joseph Tournefort in 1700, used by Johann Jakob Dillenius in 1732, and resurrected by Philip Miller in 1754. Linnaeus ([1753] 1957) rejected their segregation of the poisonous species from those that are benign; he called the poisonous plants *Rhus toxicodendron* and *R. radicans*. However, Gillis (1971) argued that *Toxicodendron* should be retained. Perhaps there is something in the older literature that supports arrow poison views, but it has not been brought into more recent studies. Although the comparison with ivy (*Hedera*) goes back to at least 1635 with Jacques Philippe Cornut's book on the plants of Canada, "poison oak" appeared in English about 1743, while "poison ivy" was first published in 1784.

In Mexico, there are several names relating to the rash caused by these plants. To the Maya, it is *chechén* (*cheché*, unseasoned or raw), meaning the rash. Similar connotation is found in *lachi gobilla* [*lachi cobilla*] (*laa*, leaf, *na-chi*, fierce, *gobilla*, chaparro or oak thicket, Zapotec, Oaxaca), and *yaga beche topa* [*yaga peche topa*, *betz-tzaj*] (*yaga*, tree,

*beche*, toast or burn, *topa*, short, Zapotec, Oaxaca). There is no translation of *bemberecua* [*bembiricua*, *bembericua*, *huembereua*] (Tarascan, Mexico), *mexie* [*mexi*, *meye*] (Otomí, Hidalgo), or *tumuraga* (Mountain Pima, Chihuahua), but they likely make a similar allusion.

Several names in Mexico refer to the problems caused by contact with *Toxicodendron*. *Fuego* (fire, Mexico) is obvious. Similarly, *yedra* or *hiedra* [*mala*, *venenosa*] ([bad, venomous] ivy, Sonora, Arizona, New Mexico) is analogous to “poison-ivy” in English. *Guadalagua* (perhaps from *guau del agua*, Mexico) may be use of a Caribbean word and notation of a preferred habitat. Several common names of irritating plants in Mexico are like *mala mujer* (bad woman) for *Toxicodendron*. Unless you are familiar with the allusion to testes, you might miss the meaning of *hincha huevos* (egg lifter, Mexico). Perhaps *dominguilla* (little Sunday, Mexico) is a notation of being embarrassed by the rash.

A loan-word is *sumaque* [*zumaque*] (sumac). This use was taken into English by the 1400s and earlier into Spanish from Arabic, *summaq* (see *Rhus*). The designation is used for members of both *Rhus* and *Toxicodendron*. While *sumaque* is applied in Mexico to poison ivy, there is no indication that people using the term confuse the poisonous with the nonpoisonous species.

Incredible as it is to those of us who are sensitive to these plants, poison ivy was used as medicine by native Americans, and it still figures in herbal remedies among some Europeans (Hocking 1997). The Houmas made a tonic and rejuvenating tea from it (Speck 1941).

Poison ivy was listed in the U.S. Pharmacopoeia from 1820 to 1905. Uses typical of these plants in that period are recorded by Porcher (1863). He wrote, “It is stimulant and narcotic, employed in paralysis and herpes; of the former disease, seventeen cases are reported by one physician to have been successfully treated with it.” He continued with cases where different physicians had used poison ivy to treat “consumptive and anasarctous patients,” “herpetic eruption,” palsy, paralysis, “chronic ophthalmia of scrofulous infants,” and ringworm. Teas from the leaves were considered antiarthritic, and leaves were once used to treat liver diseases (Foster and Duke 1990).

Porcher said, “The juice which exudes on plucking the stem makes a good indelible ink. It is dissolved by ether.” Later, he continued, “The yellow, milky juice turns dark, and forms one of the best indelible inks for marking linen.” However, producing such ink is risky because “[a]n acrimonious vapor...exhales from a growing plant of the poison oak sumach during the night, can be collected in a jar, and is capable of inflaming and blistering the skin of persons of excitable constitution who plunge their arms into it.”

All who have encountered the plant have tried remedies to cure the rash it produces. Porcher (1863) recommended, “Purging with neutral salts, the use of opium, blood-letting, and cold applications of acetate of lead are employed in case of poisoning from these plants.” Thankfully, remedies have changed. More likely learned from native Americans were Porcher’s use of the “bruised leaves of the *Collinsonia canadensis*” (Lamiaceae). Also, he commented, “*Verbena urticifolia*...is likewise considered an antidote.”

Now, there is the tendency to use corticosteroids, oral or otherwise, to treat the problem (Goodall 2002). Worse, there is a tendency among physicians to attribute any skin rash to poison ivy or poison oak (Guin et al. 1981, Stehlin 1996, McGovern et al.

2000). None of the dermatologists who treated me in Florida ever attributed my rashes to anything except poison ivy—I had to tell them the plant sources. In any event, the treatment is corticosteroids.

I learned early on to beware of the smoke of burning ivy (cf. Kollef 1995). The best solution to avoid dermatitis is to avoid the plants, but that is not easily done for swamp-stompers like me. A second-best solution to many is to control the plants. Chemicals are recommended (Paul 1993), but birds bring the seeds back rapidly, often the next season.

William T. Gillis (1933–1979) relished studying these plants because few others could. He delighted in quizzing visitors to where he lived at David Fairchild’s home, the Kampong in Miami, about poisonous plants he had growing. Eventually, he fell victim to his own pranks. He was hospitalized with an extreme case of *Toxicodendron* poisoning. Apparently, he cried “wolf” once too often.

### *Tragia*

(Linnaeus named this for Jerome Bock, 1498–1554; his name in Latin became *Hieronymus Tragus*, physician, teacher and herbalist who wrote the famous *New Kreütter Buck* in 1539)

#### *Tragia saxicola* (rock-loving) noseburn (Florida)

*Tragia saxicola* is endemic to Florida, and there are no records that it was used. Its name “noseburn” is applied as a generic name for the genus. Although that name has not been tied to a date, the original “noseburn tree” was *Daphnopsis salicifolia*, Thymeliaceae. That is a notably irritant plant known to the Aztecs as *ahuejote* (maybe *ahue* from *ahuacatl*, testicle, *jote* from *xiuitl*, herb, Náhuatl). *Daphnopsis* leaves have been used like a mustard plaster, and presumably the irritating trichomes on *Tragia* led to it becoming “noseburn.”

However, there is evidence that other members of *Tragia* have a long association with people. In Cuba, *T. volubilis* is *ortiga*, a name comparing it with the well-known European medicinal irritant *Urtica*. In Hispaniola, *T. volubilis* is *pingamoza* (child stinger), *ortiguilla* (little nettle), *picaculo* (tail sticker), and *pois gratté* (irritating pea). Leaves on *pingamoza* cause severe itching, yet the plant is used as a vermifuge. A tea of the leaves is also used to bathe sores, and a powder of the plant treats sores (Liogier 1974). The same species is called cow-itch [cowitch] or vine nettle in the Antilles (Hocking 1997). It is used in the Caribbean and Mexico as an analgesic, diuretic, and diaphoretic (Hocking 1997).

From the southwestern United States south to Central America, *T. nepetaefolia* is called *hoobox* or *popox* (black bark, Maya) and sometimes *mala mujer* (bad woman). *Popox* is used as a counterirritant in rheumatism, and a remedy for sores and cancer (Martínez 1969, Hocking 1997). To the Kiowa *T. ramosa* was *dan-sa-la* (stinging weed).

***Trema*: Nettle Tree**

(Either from Greek *trema*, hole, aperture, because of the pitted stone, or from the Latin *trema*, to quiver)

***Trema lamarckianum*.** a. Branch, b. Node to show leaf base and stipule, c. Staminate flower buds. d. Pustulate trichome from leaf surface, e. Staminate flower, side view. f. Staminate flower, longitudinally dissected, g. Floral diagram of Staminate flower, h. Pistillate flower, side view. i. Pistillate flower, longitudinally dissected, j. Floral diagram of pistillate flower, k. Fruits. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Before they built the Gumbo Limbo Nature Center in Boca Raton, there was no nettle tree (*Trema micrantha*) on the site. Shortly after the construction finished in 1984, I found a seedling nettle tree just north of the building.

Building the headquarters for the nature center had nothing to do with the appearance of nettle tree along the dunes in Palm Beach County. The first and last snow in that area

occurred in the late 1970s. Since that time, fewer winters have been severe. In the first decade or so that I was in Florida, I watched *Trema* extend its range up into southern Palm Beach County during warm years, only to be killed back during a colder winter. Because the trees grow rapidly, it was possible to chart the changes from year to year. By the time Gumbo Limbo Nature Center was established, such cold winters had ceased. The last truly cold winter in the region was late 1989 and early 1990 when large figs (*Ficus* spp.) froze to the ground in Palm Beach. The frosts, however, did not kill the nettle tree at Gumbo Limbo. Not only was that first tree still there as of August 2001, but others have appeared. Global warming shows in small, almost unnoticed vegetation changes on the margin of the tropics.

Nettle trees are tropical members of the largely temperate elm family (Ulmaceae). Linnaeus and his colleagues knew only two genera—*Ulmus* and *Celtis*. Although Linnaeus studied two species of *Trema*, he put them in the wrong genera. What is now *T. micrantha*, Linnaeus called *Rhamnus micrantha*. The other species he knew was the African and Asian *T. orientalis*, which he called *Celtis orientalis*. It fell to German botanist Johann Friedrich Gmelin (1748–1804), editor of the 13th edition of *Species Plantarum* (1788–1793), to name the third North American member of the family, *Planera aquatica*. Later, Portuguese João de Loureiro created *Trema* in his *Flora Cochinchinensis* in 1790.

A.W.Chapman (1897) first recorded *Trema* in Florida. He noted that physician Abram Paschall Garber visited Florida, hoping to improve his tuberculosis, and collected *T. micrantha* on shell mounds in Estero Bay, near Fort Myers (Lee County). *Trema lamarckianum* was found later, maybe because it has such a restricted range in the southern parts of Miami-Dade County and the Keys. Now *Trema* contains 10 to 15 species, mostly in the tropics (Mabberley 1997).

None of the early accounts of *Trema* in the United States used common names, but the Seminoles knew the plants as *silí:tá:pî* [*shen lin aape*] (*shen lin*, slimy, *aape*, stem, Mikasuki). The Creeks use the cognate *lipá:pín* (*lepakfe*, slimy, *vpe*, stem). Sturtevant (1955) reported a use in birth medicines. However, Bennett's (1997) informants indicated only that a bark decoction was used to treat recurring indigestion but not everyday problems.

By the 1930s, *Trema* was being called the “nettletree” (Small 1933), although someone had invented the book names “Florida trema” (Florida, Puerto Rico) and “West Indian trema.” “Nettle-tree” was originally applied to European *Celtis australis* and later extended to *Celtis* in North America. William Turner explained the usage in 1548 when he wrote, “It hath a leaf lyke a Nettel, therefore it may be called in englishe Nettel tree.” When the name for *Celtis* was changed to hackberry, people shifted nettle tree to *Trema*. Probably, the name was brought into the United States from the Caribbean because there *T. micrantha* is “Jamaica nettle tree.”

Perhaps the first records of *Trema* were published by Bartolome de Las Casas and Gonzalo Fernández de Oviedo y Valdés in the early 1500s. Las Casas wrote the name as *guásima*, and Oviedo penned *guasuma* (Coll y Toste 1972). Technically, that Taino name refers to *Guazuma ulmifolia* (Malvaceae); however, even now most note the similarity of *Trema* to *Guazuma*. Today, people say that *T. micrantha* is *guacimilla* [*guacimella*, *guazymillo*] [*boba*, *cimarróna*] ([crazy, wild] *guazuma*, Mexico, Cuba, Puerto Rico). To the Maya of Yucatan, *T. micrantha* is *sak pixoy* [*pixó*] (white *pixoy*), where *pixoy* is

*Guazuma ulmifolia*. The Mayan names are applied because, although they are similar, the leaves in *Trema* are white on the underside. Similarly, *T. lamarckiana* is *guasimilla* (little guazuma, Cuba), and *Guazuma* is *guásima* (Cuba).

*Guazuma* and *Trema* are also compared because they produce fibers and edible fruits. Historically, the fibers were the most important product from the trees, but other sources overshadowed and almost obscured that application. *Trema micrantha* is *atadijo* [*atadyo*] (something used for tying things, Peru), *equipal* (a seat made of fiber, from Náhuatl *icpalli*, Michoacán), *mahua blanca* (*mahuat*, fiber tree, Taino, plus Spanish *blanca*, white, Belize), and *zaparote* (from Náhuatl *zapalotl*, originally an *Agave* fiber plant, Mexico). Probably, the name *kib* (candle or wax, Maya) alludes to the use of the fiber as a wick. *Ki'ik* (*ki*, henequen fiber, *'ik*, air or wind) is another Mayan version. *Kiim* (to die, Maya) is surely transcribed incorrectly. Perhaps *cuero de toro* (bull's skin), *pellejo de vieja* (old woman's skin, Mexico), *tortolero* (twisted one, Ecuador), and *yaco de cuero* (otter skin, Oaxaca) are all allusions to bark use.

*Trema lamarckianum* is called moho bush, *bois mahaut* (*mahaut* tree, Haiti), and *T. micrantha* is *mahaut piment* (pimento *mahaut*, Haiti). All are probably based on Taino *moho* (a tree with bast fibers). Other Taino names now applied to *Trema lamarckianum* are *majagua* (Dominican Republic) and *majagua de Cuba* (Dominican Republic). In Colombia, *T. micrantha* is rendered *majagua colorada* (red fiber tree). The original application is uncertain, but now *majagua* is also used for *Hibiscus tiliaceus* and *H. elatus* because of their useful bark. According to Coll y Toste (1972), *majagua* was a forest tree, “*que produce una corteza filamentosa textil, aprovechada en la Industria de cordeleria criolla*” (that produces a filamentous bark textile, used in the Creole string industry). *Cabuya* was the Taino word for cords made from plants. It is clear from historical documents that *Guazuma ulmifolia*, both *Trema*, and probably the *Hibiscus* were involved in that industry and might have been subsumed under the name. Variants of *majagua* include *majaguillo*, *masaguilla*, *masaquila*, and *masauilla* (little *majagua*, Venezuela).

*Guazuma* and *Trema* produce edible fruits, and both are compared to *Prunus* (which see). In Cuba, *T. lamarckianum* is *capulí cimarrón* (wild cherry). Similar *T. micrantha* is *capulí* (cherry, Mexico, Guatemala), *capulín* [*capuleen*, *chapulin*] [*cimarrón*, *macho*, *monies*, *negro*] ([wild, male, country, black] cherry, Mexico, Belize, El Salvador, Honduras, Costa Rica), *capulincillo* (little cherry, El Salvador), and white *capulín* (Belize). Other allusions to the edible fruits are more circumspect. Because birds are fond of the drupes, the trees are called *fruta de paloma* (dove fruit, Argentina), *pie de paloma* (dove foot, Mexico), and *sapan* [*de paloma*] (Ecuador). Mayan people are more obtuse and say *ixpepe* [*is-pope*, *expepe*] (correctly *ix p'ep'el*, tree to hunt birds, Maya, Veracruz, Yucatan). Sometimes, people just say *guinda* (hanging, Veracruz), as fruit from a tree. Others say *T. micrantha* is a *periquiteira* (parrot tree, Brazil), or compare it with *puam* (variant of *puán*, an indigenous name for a fruit-bearing tree like *capulí*, Mexico).

Several names are shared by both *Trema*. Some applications are obvious while others are not. In Puerto Rico, *T. lamarckianum* is *cabrilla* (little goat) and *palo de cabrilla* (little goat tree), while *T. micrantha* is just *cabra* (goat) or *palo de cabra* (goat tree). These animals probably are associated with the trees because they browse the leaves (Morton 1981). Browsing is probably why *Trema* is called bo-hog (boar hog, English Antilles), *berraco* [*verracco*] (swine, Colombia), and *venaco* (for deer, Colombia).

Several names include an apparently indigenous word *memiso*, but no etymology has been found. *Miso* is Spanish for “cat,” but that seems an unlikely application. *Trema lamarckianum* is *memiso cimarrón* (wild *memiso*, Dominican Republic) or *memizo de majagua* (fiber *memiso*, Dominican Republic). *Trema micrantha* is *memiso [memizo, miso] [cimarrón, de palo]* ([wild, tree] *memiso*, Dominican Republic). French speakers compare these tropical trees with elms and say *orme petites feuilles* (little-leaf elm, Martinique, Dominique) for *T. lamarckianum*. They say either *petit orme* (little elm, French Antilles) or *bois de l'orme* (elm tree, French Antilles) for *T. micrantha*. Bahamians do not distinguish the two species by name, but note a medical application with pain-in-the-back.

To some the trees are simply a *vara blanca* (white stick, Mexico, Costa Rica). Others think of them as a *yana caspi* (*yana*, black, *caspi*, stick, Quechua, Peru). Comparisons to *Suriana maritima* made with names for *T. micrantha* such as bass cedar (Jamaica), bastard bay cedar (Belize), and wild bay-cedar (Belize) are obscure, unless perhaps they refer to the wood. Similarly, the Caribbean name “bit-root” is not clear.

The names *jaco* (Puerto Rico), *jucó* (Costa Rica), *jucui* (Mexico), and *shuco* (Tabasco, El Salvador) have been applied to *T. micrantha*. Those are probably variants of what is mostly written *joco*, a word derived from Náhuatl *xococ*, meaning bitter. This designation is usually applied to fruits that have been fermented or dried like raisins. That meaning may be akin to *ceriúva [seriúva]* (wax grape, Brazil). Perhaps false *jaco-calalu* (Puerto Rico) notes a similarity to an edible plant because *calalu* is a generic term for plants cooked as greens.

Brazilians say *quatiniaba [corindiúba, corindiba, candiúva, coatindiva, crindeúva, crindiúva, grandíúva]* (possibly Tupí). This is a name used for elm relatives, often the spiny types like *Celtis pallida*, but also applied to *T. micrantha*. The name *kurundi'y* (maybe Guaraní, Paraguay) is probably a cognate. *Quatiniaba* is perhaps akin to *raspador* (rough one, Colombia). Untranslated names are *afta Colorado* (red *afta*, Argentina), *aisegerina* (Huitoto, Peru), *dushan* (Ecuador), *kabuya koro* (Arawak, Suriname), *moniki* (Guyana), *muchichilan [muchí chilón]* (Ecuador), *shalipu* (Ecuador), *sui siyi* (Ecuador), and *tokyéwé* (Carib, Suriname).

*Churrusco* (diarrhea tree, El Salvador) and *carraspero [carrasposo]* (astringent, Venezuela) suggest a remedy for bowel problems. Maybe the same is inherent in *palo-polvora* (powder tree, Argentina) and *pão de pólvora* (powder tree, Brazil). Perhaps the name *caca [kaka]* (feces, Ecuador) indicates the same. Decoctions of *T. lamarckianum* are used in the Bahamas to relieve colds and asthma (Morton 1981). Also in the Bahamas, a remedy of the bark together with other plants is used for menstrual problems and to increase female fertility (Morton 1981). Others in the Caribbean use decoctions of the leaves for skin eruptions.

Several bioactive compounds have been isolated from different species of *Trema*, including dihydrophenanthrene and phenyldihydroisocoumarin, vitexin, paprazine and terpenoids, a flavone glycoside, simiarenone, a triterpenoid alcohol, and xanthones (Ogunkoya et al. 1972, 1973, 1977, Rakotovao et al. 1988, Ernesto et al. 2000, Dijoux-Franca et al. 2001, Tchamo et al. 2001). These and associated chemicals are known to be poisonous to camels, horses, and rabbits (Hill et al. 1985, Trueman and Powell 1991, Traverso and Driemier 2000). Similar laboratory studies indicate that *Trema* extracts are antimalarial, work against hypertension and certain nerve problems, are analgesic and

anti-inflammatory, and are used to treat gastrointestinal and urinary problems (Marquis 1974, Trovato et al. 1988, Barbera 1992, N'gouemo 1994, Grosvenor et al. 1995, Muñoz et al. 2000).

Humans may have valued the bark of *Trema* more than other parts, but birds prefer the fruit. Sit beside either species for a while when they are in fruit and you will see gray catbirds (*Dumatella carolinensis*), brown thrashers (*Toxostoma rufum*), mockingbirds (*Mimus polyglottos*), cardinals (*Cardinalis cardinalis*), and perhaps a dozen other kinds eating the orange drupes. They were using the fruits before humans were a part of the New World.

### *Triadenum*

(From Greek *tri*, three, and *adena*, gland, referring to three large glands alternating with three sets of stamens)

***Triadenum virginicum*.** From Britton and Brown 1897.

#### ***Triadenum virginicum* (of Virginia)**

Big John root (a black slave whose life was an inspiration to slaves who wanted to rebel against their masters but could not do so openly)

High John the Conqueror (“John, said to be the son of an African king, was in captivity, but he never became subservient, and his cleverness at tricking his master supplied many a story with a pointed moral. If he was a real being, he soon acquired some of the characteristics of mythical trickster figures like the Native American Coyote, the African-American Br’er Rabbit, and the West African deity known variously as Elegua, Legba, and Eshu”; from Yronwode 1999.)

Virginia marsh St. John's wort (named for St. John because his birthday was on 24 June, when the plant is supposed to bloom; the naming of the saint and the mystical figure are not accidental)

*Hypericum* and *Triadenum* have not always been considered distinct genera. For example, Small (1933) and Gleason and Cronquist (1963) separated the two, but Fernald (1950) and Steyermark (1963) put them under *Hypericum*. Now there is a consensus that they are distinct. They may be recognized by flower color—yellow in *Hypericum*, pink or reddish in *Triadenum*—although there are other differences

***Trianthema portulacastrum*.** Flowering plant, a. Portion of a flowering branch, b. Flower enlarged, c. Fruit, two-crested with seeds, d. Seed. Drawn by Lucretia Breazeale Hamilton. From Parker 1972.

(Diggs et al. 1999). Habitat sometimes distinguishes them, with *Triadenum* confined to wetlands, as the common name “marsh St. John's wort” indicates. Part of the complication of genera dates from Linnaeus who described this species as *H. virginicum* in 1759. Rafinesque transferred the species to *Triadenum* in 1837 in his *Flora Telluriana*.

There are now six to ten species of *Triadenum* in eastern North America and eastern Asia (Mabberley 1997, Diggs et al. 1999). Kartesz (1994) recognized four species in North America.

Among the indigenous tribes of North America, records have been found of only one using these plants. The Potawatomi used an infusion of leaves to treat fevers (Smith 1933).

Porcher (1863), Millspaugh (1892), and Foster and Duke (1990) do not mention the plants. However, Hocking (1997) recorded that in the southeastern states these herbs were believed to be the most potent medicine of the forest. Many people carried a piece of the plant in a pocket as a charm. Among the blacks, a leaf tea was taken for chest diseases, the flowers were used to treat colic, and an ointment was used for wounds, sores, and swellings (Hocking 1997).

Nothing has been found published on the chemistry of the America species. However, *T. japonicum* is reasonably well studied, and it has only betulinic acid reported. That chemical is considered anti-HIV, anti-carcinomic, anti-inflammatory, antimalarial, antiplasmodial, antitumor, antiviral, cytotoxic, and a prostaglandin-synthesis inhibitor (Duke 2003).

The name “High John the Conqueror” is not confined to this species, but also applied to *Ipomoea* (which see).

### *Trianthema*

(From Greek *treis*, three, and *anthemon*, flower)

***Trianthema portulacastrum*** (with flowers like *Portulaca*, purslane)

[desert] horse purslane [horsepurslane] (a notation that it is not the “true” purslane, *Portulaca*, Arizona, Florida, Texas, Sonora, Bahamas)  
*kasvañ* [*kashviñ*, *kashvañ*] (Akimel O’odham)

[Pima], Tohono O’odham [Papago], Arizona)

pigweed (usually applied to *Amaranthus*, Arizona)

*pourpier couran* (running purslane, Martinique; also used for *Kallstroemia maxima*)

sea-purslane (a name usually given to *Sesuvium*; in both cases it compares the plants with purslane or *Portulaca*)

*tostón* (a name shared with *Boerhavia*, Cuba)

*verdolaga [blanca]* ([white] purslane, Spanish, Arizona, Dominican Republic, Río Mayo, Sonora, Texas); *verdolaga de hoja ancha [de mar]* (narrow

leaf [seaside] purslane, Puerto Rico); *verdolagas de cochi* (Sonora)

*verdolaga de sapo* (toad purslane, Akimel O’odham [Pima], Sonora);

*yerba de sapo* (toad herb)

Linnaeus ([1753] 1957) knew a single species of *Trianthema*, and described *T. portulacastrum* from specimens collected in Jamaica and Curaçao. Before him, Paul Hermann had it in cultivation in the Netherlands before 1689; Hans Sloane collected it in Jamaica after 1686; and John Ray cultivated it in England by 1704. The genus is now known to contain about 17 species in warm parts of the world, although most species are in Australia (12 species, 10 endemic) (Bogle 1970, Mabberley 1997).

These plants have been recorded as being eaten raw as a salad in New Mexico and served as greens in Arizona (Curtin 1949). Curtin’s report of these plants may be correct, but it is probably through confusion with *Portulaca oleracea* (Rea 1997, Hodgson 2001).

***Trichostigma octandrum*.** a. Flowering branch, b. Flower, front-side view. c. Flower, longitudinally dissected, d. Floral diagram, e. Fruit. Drawn by Priscilla Fawcett. From Correll and Correll 1982.

Names throughout the range suggest possible confusion.

However, the plants were (and maybe are) eaten in Asia. Hedrick (1919) noted that they were a potherb in India in the 1800s, although in times of hunger. Hedrick (1919) further warned that they might produce diarrhea and paralysis if eaten in abundance. Watt ([1889] 1972) recorded edibility and medicinal uses of four other species in India. More recently, the plants have been recorded as diuretic (Vohora et al. 1983, Hocking 1997). Some contain alkaloids, and others are used for soap (Mabberley 1997).

*Trianthema* contains trainthemine, saponins, and tetraterpenoids (Bogle 1970, Hocking 1997, Nawaz et al. 2001). Studies in Asia have shown that the plants act as antifungal agents (Nawaz et al. 2001), and that they have potential as antihepatotoxics (Mandal et al. 1998), antiulcerogenics (Akhtar and Ahmad 1995), and to inhibit DNA damage and chromosomal aberrations (Sarkar et al. 1999), inhibit hepatocarcinogenesis (Bhattacharya and Chatterjee 1998a, 1999), and restore the antioxidant defense enzyme levels and hepatic biotransformation patterns (Bhattacharya and Chatterjee 1998b).

### ***Trichostigma*: Hoop Vine—The Plant That Wasn't There**

(From Greek *trichos*, hair, *stigma*, the stigma, having hairlike projections from the stigma).

Back in the early 1970s the avid field botanist George N. Avery (1922–1983), of Fairchild Tropical Garden, told me that he had found *Trichostigma octandrum* on Chokoloskee Island just south of Everglades City. At the time, David McJunkin and I

were studying the ethnoflora of that island on the northern fringe of the 10,000 Islands. It should have been simple enough to find the plants. Their stems grow to about 10 m long, scrambling over other plants to form a blanket of greenery. The stems are woody and pliant and grow larger in diameter than a person's thumb. We scoured every inch of the island but did not find this climber, now called "hoop vine" in Florida.

Later, in 1982, John Popenoe and Don Correll (1908–1983), also of Fairchild Tropical Garden, collected the vines on Chokoloskee. I went back and still could not find it. In March of 2000, Florida Atlantic University graduate student, Mike Anderson, brought in a sterile sample from Conservation Area 3 in Broward County. The sample looked to me like a woody "rougeberry" (*Rivina humilis*). Mike had found the elusive hoop vine.

It seems that Linnaeus thought the plant looked like rougeberry too back in 1756 when he named it *Rivina octandra* (*Rivina*, named for German botanist A.G. Rivinus, 1652–1723; *octandra*, with eight anthers). Subsequently, in 1909, another German biologist, Hans P.H. Walter (1882–?), realized that the species belonged in a separate genus. He discovered that the Frenchman Achille Richard (1794–1852) had created the proper home for the species in 1845, and so Walter moved Linnaeus's species name (*octandra*) to *Trichostigma*. So far as Mike and I could learn, we are the only biologists to see the live plants in Florida since 1982.

There has always been an unusual "hit-and-miss" story in the United States behind this relative of rougeberry and pokeweed (*Phytolacca americana*). Chapman's southeastern flora (1897) did not include the species. Later, when John K. Small (1933) wrote an updated southeastern flora, the species was there. Hoop vine has only been collected two or three times since, and it is now known from Collier, Monroe, and Broward Counties. Mike's discovery was a county record.

I cannot help but wonder, "Is this a rare native or an exotic species?" Indeed, the plants were so rampant when Mike found them, he was afraid he had discovered yet another alien species running amuck in the Everglades. After seeing the vigor with which hoop vine grows, I could even better understand his fear.

We were not the first to question this climber's nativity in this northern fringe of its range. Julia Morton (1981) wrote in her atlas on medicinal plants of the Americas that hoop vine was naturalized in the Bahamas. George Avery thought people might have introduced *Trichostigma* onto Chokoloskee Island (Austin and McJunkin 1978).

Why would someone introduce this plant? A search reveals that people have used the plant in several ways throughout its range from Cuba to Venezuela and Peru. The stems have been used to weave baskets and to make barrel hoops (Liogier 1974). In Cuba, it is *bejuco canesta* (basket vine) and *guaniquí* (Taino). On French-speaking islands it is *liane pannier* (basket vine) or *liane a barriques* (barrel or cask vine, Guadeloupe, Martinique). On English-speaking islands, reaching from Jamaica to Barbados, it is black basket wythe [wiss, with], cooper wythe, and hoop with. Some other names appear to allude to medicinal uses, like *bonbon codine* (codeine candy), *bois a terre* (wild bush), and *liane a terre* (wild vine, Guadeloupe, Martinique). For some reason, the plant was important enough to be given names like *sotacaballo* (substitute horse, in Costa Rica), *pabellón* (pavilion) or *pabellón del rey* (king's pavilion, in the Dominican Republic), *látigo* (lariat for catching horses, Guatemala), *entiil aaxux ts'aah* (like garlic vine, Huastec, Veracruz), and *zamura* (little vulture).

Colombians use the leaves to help cure wounds (Morton 1981). Hispaniolans apply leaf decoctions to help someone overcome suffocation or choking and to treat asthma (Liogier 1974). Fruits and stems have the same uses. It is medicinal also among the Mayan speakers of Mexico. Most surprisingly, people grow it. Perhaps they grow it for medicine or weaving, but some apparently find it ornamental. This species was cultivated in the Bahamas in the 1970s, and the South American species *Trichostigma peruviana* is listed in *Hortus Third* (Hortorium 1976).

Nothing seems to be known of the bioactive compounds in this species, but several of its relatives are notorious chemical factories. Two genera, *Petiveria* and *Phytolacca*, are best known. Among their active compounds are several saponins, or soaplike compounds. If hoop vines are anything like those two, there is no wonder they have been used in medicines. Extracts of *Petiveria* have shown promise in treatment of protozoal infections, particularly those caused by *Trypanosoma cruzi*, which causes Chagas' disease in the tropics. That same plant may be useful in controlling tumors (mitogenic). Several species of *Phytolacca* have been studied and show promise against mitogenesis, in treating human immunodeficiency virus (HIV), in fighting vector-borne diseases in animals, and in killing disease-carrying snails (Berger et al. 1998, Rajamohan et al. 1999).

Still, the names *bonbon coq d'Inde* (Indian rooster candy), *bejuco de paloma* (dove vine), *pira de guacharaca* (chachalaca's nest; the chachalaca, genus *Ortalis*, is a bird somewhat resembling a chicken), *guacamaya* (macaw), and *murette* (little mulberry) show that people from Colombia to Hispaniola recognize that the fruits are spread by birds.

So, did the species come to Florida with people or in the stomachs of birds? Is it a rare and endangered native or an alien? We do not know. But, after a hiatus of 18 years, we know the species is still in Florida. It shows up about every couple of decades. Maybe this is a plant that appears only periodically, like the legendary Scottish village *Brigadoon*. Perhaps, like that village, the plants appear, thrive a short time, and then disappear back into the mists.

### *Triodanis*

(From Greek *tri*, three, and *odontos*, teeth, possibly referring to the three calyx lobes of some flowers)

***Triodanis perfoliata*.** From Britton and Brown 1898.

***Triodanis perfoliata*** (perfoliate or having the stems appear to grow through the leaves)

clasping bell-flower [bellflower] (“bell-flower,” a name originally given to *Campanula* in Europe, in use by 1578 when Henry Lyte translated Dodoens’s *Cruydeboek* of 1554 into English)

clasping Venus’s looking-glass (“looking-glass” was an alternate name for a mirror in use by 1526; “Lady’s looking-glass” or “Venus’ looking-glass” was in use by 1622, originally for *Campanula speculum*, and then later for other plants)

hens-and-chickens (in Europe, “hens-and-chickens” was the common name of the constellation Pleides by 1535; later it became the name of several plants, and by 1794 it was being applied to some daisies, Texas)

For decades the name *Triodanis* was largely ignored with preference given instead to *Specularia* (from Latin *specula*, looking-glass). *Specularia*, for example, was used by Fernald (1950). There was good precedent in using that name because of the European Venus’s looking-glass, *Legousia speculum-veneris*, that has been put in synonymy with *Specularia*. Geoffrey Grigson wrote in 1955, “When the long capsule opens, the looking-glasses of the Virgin or Venus are revealed, the seeds of which are oval or elliptical, pale brown, exquisitely polished, and pellucid like a speculum” (Coffey 1993). That description really does not apply to the American plants, and it is odd that it was applied.

Rafinesque created *Triodanis* in 1894 in a book published after his death. McVaugh (1945, 1949) used that genus, but others disagreed with him. Now *Triodanis* is circumscribed to include six species in North America and one in the Mediterranean (Rosatti 1986, Mabberley 1997). The species in the Old World is *T. falcata*, and it too has been placed in both *Specularia* and *Legousia*.

*Triodanis perfoliata* was named by Linnaeus ([1753] 1957). He thought it was a *Campanula*, as had his predecessors. The plants were first known in Europe when Robert

Morrison reported them in a list of plants cultivated in London in 1686. From that point, the herbs seem to have been continuously cultivated there and in France, the Netherlands, and Sweden (Linnaeus [1753] 1957).

The Cherokee used roots in a drink to relieve dyspepsia from overeating (Hamel and Chiltoskey 1975). The Meskwaki used it as an emetic and commented, "it will make one sick all day long." They also smoked it at ceremonies (Moerman 1998).

No comments have been found on poisons in the plants by Hardin and Arena (1974), Perkins and Payne (1978), Turner and Szczawinski (1991), or Foster and Caras (1994). Therefore, the plants must not be too poisonous. However, given the toxic chemicals known to occur in *Campanula* and *Lobelia* (which see), caution is advised.

### *Tripsacum*

(Origin obscure, perhaps from Greek *tribein*, to rub, perhaps an allusion to the polished spike-like inflorescence; Quattrocchi 1999 suggested it might be Greek *tripsis*, rubbing, and *psakas*, a grain)

*Tripsacum dactyloides*. Drawn by Mary Wright Gill and Agnes Chase. From Hitchcock and Chase 1950.

*Tripsacum dactyloides* (fingerlike, an allusion to the branches of the inflorescence)

Fakahatchee grass [Fakahatcheegrass] (a name applied to these plants by the horticulture industry in spite of the fact that the plants grow from New England and Michigan south)  
[eastern] gama [gamma] grass [gamagrass] sesame-grass

***Tripsacum floridanum*** (of Florida) Florida mock gamagrass

At the Ozark Bluff-Dweller site in Arkansas, Melvin Gilmore found gama-grass. He wrote: “A puzzling fact is the presence of great quantities of remains of *Tripsacum dactyloides* L. in the Bluff-Dweller habitations. The seeds would undoubtedly be good for food, but they are so deeply imbedded in the hard, tough rachis that one cannot see how the Indians could have separated them. The hulls might possibly have been cracked by pounding in a mortar and then winnowed out” (Gilmore 1931).

Mary Eubanks (2001) commented that it is not necessary to crack the hulls with a mortar to extract the kernel from gama-grass. She tells me “how easy it actually is to extract the kernel from the fruitcase because the outer glume does not overlap the inner glume. You can quite literally take your fingernail and easily pop open the fruitcase of *Tripsacum*.”

Kindscher (1987) found a report that the “popped kernels of *Tripsacum* species are almost indistinguishable from those of open-pollinated strawberry popcorn.” However, even that may have been the least common preparation of gama-grass. Galinat and Craighead (1964) reported that local Floridians carried “a pocket full of fruit cases to chew when out on hunting trips.” The species they carried was the second species in southern Florida, *T. floridanum*. If it was used as food, certainly the same people used *T. dactyloides* because it is more common and produces more seeds. They should be eaten because the seeds contain, “10X the protein of corn.” They are “delicious raw, roasted, or popped. I eat it. It’s more flavorful than corn” (Mary Eubanks, personal communication Mar. 2003).

## ***Typha***

(Greek *typhe*, *tiphe* applied by Theophrastus, 372–287 B.C., Dioscorides, fl. A.D. 40–80, and Aristotle, 372–287 B.C., to a kind of aquatic plant used for stuffing beds and bolsters)

***Typha domingensis*** (from Santo Domingo)

***Typha latifolia*** (broad-leaved)

*aba'kweûck* (shelter weed, Potawatomi); *apuk'we* (Ojibwa); *pakwe'ûck* [pukyuk] (Prairie Potawatomi)

*aguapá* (from Tewa 'aguap'a, New Mexico, Mexico)

*beecho* [peecho] (mat or matting, or bundle of reeds, Zapotec, Oaxaca)

*biwiê'skwînú* (fruit for baby's bed, Potawatomi)

*bodan-dubh* (black penis, Gaelic)

bull-rush (USA, England)

cat-tail [cattail, cattes taylor] (from at least 1558, when Turner recorded the name as “cattis taylor,” and “cats taile,” USA and England to Panama)

*Typha*. a. *Typha domingensis*. b. *Typha latifolia*. From Institute of Food and Agricultural Sciences.

*cuigeal nam-ban-sithe* (*cuigeal*, staff, *nam*, of the, *ban-sithe*, female fairy, Gaelic); *cuigeal nan-lo-gann* (*cuigeal*, staff, *nan*, of the, *lo*, day, *gann*, little, Gaelic); *cuile* (Gaelic)

down [cat-tail down] (referring to the fluff on the seeds which has been used like duck feathers in stuffing pillows, etc., Bahamas)

elephant grass (Belize)

*énea* [*éneas*, *anea*, *aneas*] (copper colored, Dominican Republic, Panama, Colombia); *yerba de éneas* (copper colored herb, Puerto Rico)

*espadaxa* (having a spike, the inflorescence, Colombia)

[*grand*] *gros jonc* [*natte*] (big [matting] rush, Haiti)

*hashuk pancha* (*hashuk*, herb, *pancha*, cattail; *panti* is the upper end of the stalk where the “down” grows, Choctaw); *hassikbacilká* (*hassí*, herb, Koasati)

*hawahawa* (Pawnee)

*her be a masses* (mace herb, French); *macío* (mace, Spanish); *masse* (mace, from 1542, French); *massette* (little mace, Guadeloupe,

Martinique); *mazzo-sorda* (mute or deaf [blunt?] mace, Italian); reed-mace [reedmace] (as “reide mace” by 1558 or before)

*hoski* (Chickasaw)

*jonc* (based on the Latin *iuncus*, for a rush, derived from *iugere*, to tie or bind, from the use of stems for tying, Haiti, Guadeloupe, Martinique); *junco* [*de ester a, de pasion*] ([marsh] rush [for suffering], Colombia)

*kalakalaru* (Arawak, Suriname); *kara* (Carib, Suriname)

*kirit-tacharush* (*kirit*, eye, *tacharush*, itch, so named because flying down causes itching of eyes, Pawnee)

*kowi' hasimbish* (*kowi'* cat, *hasimbish*, tail, Chickasaw)

*ksho-hin* (*ksho*, prairie chicken, *Tampanuchus cupido*, *hin*, feather; plucked down resembles finer feathers from the prairie chicken, Winnebago)

*mi-ke'-the-stse-dse* [*mi-ke'-the-stse-e*] (Osage; one of their life symbols, representing the water part of the earth)

*nathita<sup>h</sup> tlho<sup>h</sup>* (Slave, Canada); *tlh'ogh k'a* (fat grass, refers to the shoots, Chipewyan, Canada)

*otawaskwa* (water-edge plant, Cree)

*pashini* [*pasí: ní*] (Mikasuki); *passenv* [*pashinat*] (Creek)

*puh* (Maya)

*roseau* (reed, Houma, Louisiana, Guadeloupe, Martinique)

*sacate ignea* (burning grass, Belize)

slag (slippery with mud, English dialectic, Bahamas)

*tule* (from *tollin* or *tullin*, Náhuatl)

*wahab' igaskonthe* (*wahaba*, corn, *igaskonthe*, similar, referring to the appearance of the floral spikes synchronously with maturing of corn, Omaha-Ponca)

*wihuta-hu* (*wihuta*, bottom of tipi, *hu*, plant, Dakota)

The name “reed-mace” for *Typha latifolia* is the key to understanding the Romance language names for these herbs. According to William Turner in 1562, “It maye be called rede mace, because boys vse it in theyr handes in the stede of a mace.” The mace (Old French, *masse*; Portuguese, *massa* or *maça*; Italian, *mazza*, Spanish, *maza*) was a weapon of war. Apparently, boys “playing war” used a cat-tail substitute and originated the “reed-mace.”

People all over the world have used these plants—not just small boys. Names tend to be applied indiscriminately to either of the species, with *T. latifolia* the one from Europe, and *T. domingensis* dominant in southern North America. In Florida, the pollen of *Typha* was in the archaeological remains of Fort Center, formerly inhabited by Glades people (Hogan 1978). Because the plants are wind pollinated, that cannot be taken as firm evidence they were using the plants, but they probably were. Oddly, most people in North America except the Muskogean tribes, Houma excepted, left records of using *Typha* (Moerman 1998). Maybe the Muskogean absence is explained by the belief that handling the stems would “make the stomach big” (Bennett 1997). Still, there is a mat found in Tennessee caves that was within the geographic range of the more northern Muskogeans (Whitford 1941). In the Missouri River region, the Omaha-Ponca

used the down as dressings for burns and scalds; on infants to prevent chafing, like talcum; and fillings for pillows, padding for cradle boards, and quilting in baby wrappings. Stems were made into ceremonial objects called *niniba weawan* for the Wawan ceremony. *Typha* down or fluff was used to dry the mother and infant at birth. Pads of cat-tail down were used as diapers (Gilmore 1919). Even Sacagawea, the Shoshoni guide with the Lewis and Clark expedition, used the down as a diaper for her newborn in the Mandan village in North Dakota (De Voto 1981). The Omaha-Ponca uses essentially summarize those of other people. Seminole relatives the Houma boiled stalks into a tea to treat whooping cough (Speck 1941).

It is impossible to separate what Europeans brought from Old World uses of *Typha* and what they learned from the indigenous people. Both knew that the root could be peeled, boiled, and eaten as potatoes or macerated and boiled for sweet syrup. The root also yields flour, and the pithy portion where root joins sprouting new leaves is boiled and eaten. Young shoots may be eaten in the spring (Fernald et al. 1958, Morton 1968b, Liogier 1974). Also the pollen is used as food and may be substituted for *Lycopodiella* spores (which see).

Curtin (1947) recounted how the Paiute ate the seeds. These people spread the fruits on an open spot of ground and set fire to them. When the fluff and other material burned away, the toasted seeds remained, and could then be eaten.

In Central America and the Caribbean, the *lana* (wool) from the spikes has been used to stuff pillows and cushions (Liogier 1974, Ayensu 1981). Leaves were once used for thatching, the stem is diuretic, and some consider the root aphrodisiac (Liogier 1974).

*Typha latifolia* is sold in Mexican-American herbal stores as *aguapá*, and is used as a diuretic and for insect bites. Spikes were dipped in fat and burned as torches in colonial times (Hocking 1997). *Typha domingensis* is the source of *tabua* fibers, a substitute for kapok in Brazil (Hocking 1997).

# U

## *Ulmus*

(The classical Latin name for the elm tree)

***Ulmus.*** *Ulmus americana* (upper).  
*Ulmus rubra* (lower). Both from  
Sargent 1905.

*é-hiu* (Osage)

elm (derived from Latin *ulmus*; occurs about A.D. 1000 in Anglo-Saxon, with variations including *elme*, *elem*, *ellum*, *ulm*, *ulme*); *alim* (the first letter of the Gaelic alphabet); *alm* (Danish, Swedish, Norwegian); *álmr* (Old Norse); Elme (Turner [1548] 1965); *iep* or *olm* (Dutch); *olmo* (Italian, Spanish); *orme* (Quebec, France); *Ulme* (German); *u'ulum* (to bind, Akkadian)

*lamequeiro* (elm tree, probably based on Gaelic, Spanish)

*leamhan* (pronounced “leven,” *U. glabra*, the Wych [supple, pliant] elm, Gaelic); *llwyfan* (pronounced “leven,” *U. glabra*, Welsh)

*ptelea* (Greek)

*ucha'pesk* (Plains Cree)

***Ulmus alata*** (winged)

[cork, corky, mountain, red, small-leaf, southern, water, wing, winged] elm

*flygel-alm* (winged elm, Norwegian); *vleugel iep* (winged elm, Dutch)

*olmo corcho* (cork elm, Spanish); *olmo sughero* (cork elm, Italian); *orme liege* (cork elm, French)

*silhobá* (Koasati); *úhawhu* (said to be Muskogee; Martin and Mauldin 2000 said the word *vhahwv* referred to the walnut, wood, nut, and tree); wahoo [whahoo, wahoo elm] (variant of Muskogee name, adapted into English by 1770); *whohao* (used by Williams [1837] 1962)

winged ash (an anomalous application)

witch elm (supple or pliant elm, from Old Teutonic *wik*, through Old English *wicca*, with the variant spelling of *wych*, the European name for *U. glabra*)

***Ulmus americana*** (of America)

*Amerikaanse treur-iep* [*witte iep*] (American weeping [white] elm, Dutch)

*amerikansk hang-alm* (American hanging elm, Norwegian; could this be an indication of historic lynch parties?)

*amerikansk vit-alm* (American white elm, Norwegian, Canada, USA)

*anib* (Potawatomi)

*baksá* (thread, Koasati)

*da-wa-tsi:-lai* (Cherokee)

[American, American weeping, common, Florida, gray, gray hard, rock, soft, swamp, water, white] elm

*ezhon zhon* [*ezhon zhon ska*] (*ezhon*, elm, *zhon*, wood, *ska*, white, Omaha-Ponca)

*ohóskere* (Onondaga)

*olmo bianco americano* (American white elm, Italian, Canada, USA);

*olmo bianco americano* (American white elm, Spanish, Canada, USA);

*olmo lloron americano* (American weeping elm, Spanish); *olmo piangente*

*americano* (American white elm, Italian); orhamwood (apparently a

mixture of French, *orham*=*orme*, and English, Canada); *orme blanc*

[*americain*, *d’Amerique*] ([American] white elm, French, Canada); *orme*

*maigre* (meager elm, French); *orme pleureur americain* (American

weeping elm, French)

*pe chan* (*pe*, elm, *chan*, wood, Dakota)

springwood (USA) *taitsako taka* (*taitsako*, elm, *taka*, white, Pawnee)

*úhawhu* (said to be the Creek word for *Ulmus*)

*alata*; however, the Dakota *wahú*, arrowwood, was applied to *Euonymus*, and is not cognate)

*yfoshó* [*afósho*, *tyfoshó*] (maybe the source of “wahoo” in English, Muskogee)

***Ulmus rubra*** (red)

*achgükbi* (Delaware); *cací’búb* (slippery bark, Potawatomi);

*osasha’kúp* (Prairie Potawatomi)

*afósho* (Muskogee); *to-fósho* (*to* is an abbreviated form of *eto*, tree, Muskogee); *tohto* (Choctaw)

*Amerikaanse rode iep* (American red elm, Dutch, Canada, USA);  
*amerikansk rod-alm* (American red elm, Norwegian, Canada, USA)

*atcinni pihi ayudi* (*atcinni*, grease, *pihi*, smells good, *ayudi*, tree, Biloxi)

*balop* (Chicksaw); *balup* (Choctaw); *lopakv* [*lupákv*, *lupaka*] (Muskogee)

*é-hiu hin-dse gthi-gthi-e* (*é-hiu*, elm, *hin-dse*, linden, *gthi-gthi-e*, slippery; Hunter said it was *hon-kos-kao-ga-sha*, it won't go down, Osage); *ezhon zhide* (*ezhon*, elm, *zhide*, red, Omaha-Ponca); *ezhon zhide gthogthide* (*ezhon*, elm, *zhide*, red, *gthogthide*, slippery, Omaha-Ponca)

[gray, Indian, red, red-wooded, rock, slippery, slippery-bark, soft, sweet] elm (Canada, Europe, USA)

*Fuchsbaum* (fox elm, German)

*gochráta* (Onondaga)

it slips (English?, North America)

*kaw-la* [*ga'dal-a*] (buffalo tree, because buffalo congregate under its shade, Kiowa)

*kee-awdl-ya-eep-eep* (Kiowa)

moose elm (so called because moose, *Alces alces*, browse on young twigs and foliage, Canada)

*olmo rojo americano* (American red elm, Spanish, Canada, USA);

*olmo rosso americano* (American red elm, Italian, Canada, USA)

*oo-hoosk-ah* (Onondaga)

*orme fauve* [*gras, rouge, rouge d'Amerique*] (fawn-colored [fat, red, American red] elm, French, Canada, USA)

*pe tututupa* [*pe tutuntu npa*] (*pe*, elm, Dakota, Teton)

*taitsako pahat* (*taitsako*, elm, *pahat*, red, Pawnee)

*taw-a* [*ta'ä, te-aw-ya-daw*] (saddle tree, because older saddles were made with a forked branch, Kiowa)

*wakidikidik* (Winnebago)

*yap tcu 'wi-kare* (tree slipping [slimy], Catawba)

When I was growing up in western Kentucky, elm trees of several species were common. Larger trees were favorite places for adults and children. Streets were lined with elms, and where old specimens grew, people congregated in their shaded havens. As youngsters, we make bows from the branches, and twisted the inner bark to make bowstrings. We had no idea that in using the bark for string we were reenacting scenes as old as the Hopwellian cultures of the area's past.

Then, in the early 1960s, trees began dying. First one branch would turn brown, and soon the whole tree died. We learned that the malady was caused by the "Dutch elm disease" that had been accidentally introduced from Asia by way of infected timber from Holland. Beetles quickly spread the fungus, *Ophiostoma* (*Ceratocystis*) *ulmi*, from one tree to the next. The disease had almost annihilated the American elms by the early 1970s, and it began eliminating other species. The same thing happened in Europe, where in Great Britain 11 million trees were killed by the fungus between 1970 and 1978 (Mabberley 1997). The change in appearance of streets and other parts of cities was

phenomenal. Economic losses associated with cultivated plants alone were staggering. At one point there were 400,000 diseased elms in Denver, Colorado, with an estimated cost of \$500 million to remove them (Hocking 1997).

The change caused by loss of elms was the latest episode in the story of people's interaction with the genus. Mabberley (1997) suggests that by ca. 3000 B.C. Europeans had begun manipulating the trees through pollarding and other management activities that altered elm frequency. There are seven native species in North America and six in Europe (Mabberley 1997). In total, *Ulmus* contains 20–40 species, with most in Eurasia (Mabberley 1997, Sherman-Broyles 1997).

All of Florida's species have a long association with indigenous people. Although no tribes seem to have been recorded as using *U. alata*, its Creek name is *úhawhu*. Surely, they used at least the wood. Wood was perhaps the most frequent item taken from elms. The wood from the different species is so similar that few can distinguish them. For example, Harrar and Harrar (1946) wrote that milled boards of *U. alata* "are mixed with those of other elms and thus lose their identify in the trade." The same is true of other species. Wood is close grained, heavy, hard, and light brown. Wood of all species is difficult to split (Uphof 1968).

Wood from elms was important to several tribes. More information has been found on Great Plains people than others, but it is likely southeastern tribes used it similarly (Gilmore 1919, Moerman 1998). Posts were used for building lodges by the Dakota, Lakota, Omaha, Pawnee, and Ponca. The same tribes used it to make mortars and pestles to grind corn, medicines, or perfumes, fuel, and saddle trees. Vines (1977) indicated that indigenous people (no tribes mentioned) used elm wood for canoes.

Settlers too used the wood in many ways. Elm was used for agriculture implements, baskets, boats and shipbuilding, boxes, cabinets, car construction, cooperage, crates, flooring, framework, fuel, furniture, handles, hubs of wheels, posts, saddle trees, sills, sporting goods, stock staves, ties, tool handles, toys, trunks, vehicles, veneer, and woodenware (Uphof 1968, Vines 1977, Hocking 1997).

Bark was probably second in importance to many tribes (Gilmore 1919, Yanovsky 1936, King 1984, Moerman 1998). Among the Ojibwa and Potawatomi, sheets of the bark were used to cover wigwams. Kalm ([1753–1761] 1972) described how his Mohegan guides made a canoe for them with the bark of *U. americana*, caulking the ends with *U. rubra* fibers. He wrote: "Of the [white elm] the boats made use of here are commonly made, it being tougher than the bark of any other tree. With the bark of the hickory, which is employed as bast, they sew the elm-bark together, and with the bark of the red elm they join the ends of the boat so close as to keep the water out. ... That which we made was big enough to bear four persons, with our baggage, which weighed somewhat more than a man."

The Cherokee, Menomini, Omaha, Pawnee, Ponca, Potawatomi, and Winnebago used inner bark fibers to make baskets, dogsled harnesses, matting, nets, ropes and cords, and snowshoe laces. The Iroquois made dogsled harnesses from the bark. One of the Iroquois tribes, the Onondaga, used "the bast like hemp & oakam to stop leaks" (Zeisberger and Horsford 1887). When the outer bark had "weathered for several years till it glows with phosphorescence in the darkness," it was used to catch the spark in making fire among the Missouri River tribes (Gilmore 1919).

Those uses of the inner bark go back to the Hopwellian cultures, and Whitford (1941) was the first to note elm fibers in their woven fabrics in Ohio. Gilmore (1931) found elm fibers among the materials left by the Ozark Bluff-Dwellers in Arkansas, and Whitford (1941) also identified both *U. americana* and *U. rubra* in Iroquois burden straps.

Settlers learned from the indigenous uses. During the Civil War, the inner bark was touted as twine to fasten cotton bale covers. Porcher (1863) quoted a Montgomery County, Alabama, newspaper as saying, "Mr. [T.J.] Howard has used the wahoo rope with great success in bagging cotton on Col. Baldwin's place, and we can safely recommend his contrivance to the attention of planters. ...The manner of using the rope made of wahoo bark is altogether similar to that which has been in ordinary use." Later, the inner bark still was used locally for baling twine (Harrar and Harrar 1946).

Elms are also a source of food. John D. Hunter wrote in 1823 that he found the bark nutritive and had "subsisted for days on it" while living among the tribes in the Ozark region (Hunter [1823] 1973). Yanovsky (1936) found bark had been eaten by tribes in New York. The Cheyenne and Kiowa drank a "tea" of the inner bark like coffee and also stored it for winter use (Moerman 1998). They used the bark in much the same way as pioneers who used the bark to quench thirst (Vines 1977). The Omaha cooked bark with the fat of buffalo as a preservative to keep it from becoming rancid and to add flavor. Once the fat was rendered, children ate the bark pieces.

The most frequent medical use by indigenous people seems to have been to treat wounds, burns, inflammation, and other skin problems. While there are more records of *U. americana* and *U. rubra* than for *U. alata*, all three were used to treat medical problems. In 1714, John Lawson wrote: "The Indians take the Bark of [the elm] Root and beat it, whilst green, to a Pulp, and then dry it. ...This they use as a Sovereign Remedy to heal a Cut or green Wound, or any thing that is not corrupted. It is of a very glutinous Quality" (Lawson in Vogel 1970).

Southeastern uses include the Choctaw who made a decoction of *U. americana* inner bark to relieve menstrual cramps (Taylor 1940). The Houma mixed the bark with red oak (*Quercus falcata*) to treat dysentery (Speck 1941). The Koasati made a decoction of the bark to heal gunshot wounds (Taylor 1940). The Creeks used *Ulmus* to treat toothache (Swanton 1928a).

*Ulmus rubra* was used similarly. The Alabama and Creek made a decoction of the bark and believed that it induced labor (Swanton 1928a). The Cherokee made remedies of it to soothe the stomach, relieve dysentery, coughs, sore eyes, heartburn, catarrh, quinsies (inflamed uvula), consumption, and breast complaints. They also made a poultice to treat burns (Hamel and Chiltoskey 1975). Americans learned from indigenous people, and physicians used the bark as a poultice for gunshot wounds during the Revolutionary War and the Civil War (Hocking 1997). Sap of *U. rubra* is still used by Oklahoma Seminole women as a vaginal lubricant before sex and also in childbirth to ease delivery (Howard 1984).

Dried inner bark of *U. rubra* is mucilaginous and aromatic, and it contains an aromatic principle like fenugreek in odor (Hocking 1997). The bark was in the U.S. Pharmacopoeia from 1820 to 1936 and in the National Formulary between 1936 and 1960 (Vogel 1970). Those lists considered it protective, demulcent, and emollient. While the bark is no longer "official," various preparations of it are still marketed (Sherman-Broyles 1997).

American elm life spans were 150 to 175 years and their canopies created favored sites for special events. This use began with indigenous people and continued with settlers. One of these old trees was the Great Elm at Palmer, Massachusetts. There General George Washington stood in its shade to address his troops 3 days before he took command of the Continental Army. Another historic tree was the Penn Treaty Elm that blew down in 1810 (Harrar and Harrar 1946). Surely, one of the most notorious trees was the Daniel Boone Judgment Tree. After “settling down,” Boone became a judge and held court under that venerable old tree. According to the legend, he selected that particular tree because it had served as a location for meetings by the indigenous people before him. When Boone deemed an individual guilty, the tree’s branches allowed the hangman to do his job without moving. One of the offspring of that tree was reaching maturity at the Missouri Botanical Garden in the late 1960s when I watched as Dutch elm disease killed it. Our lives were greatly impoverished by the introduction of the disease that shortened the life span of elms.

### *Uvularia*

(From Latin *uvula*, the flowers hanging like the uvula from the palate)

***Uvularia perfoliata*.** From Britton and Brown 1896.

bellwort (a name usually applied to *Campanula*); merry-bells  
wild-oats

***Uvularia perfoliata*** (perfoliate or having the stems appear to grow through the leaves)

[cow, hay, straw] bells

[fragrant, mealy, perfoliate] bellwort

crow’s foot (used by John Bartram in 1751)

Mohawk-weed (“Mohawk” one of the Five Nations of the Iroquois in upper New York)  
 strawflower

*Uvularia sessiliflora* (sessile-leaved, or leaf without stalks)  
 cornflower (Maine)  
 crow’s foot (used by John Bartram in 1751)  
 sessile-leaf bellwort  
 straw-lillies (Connecticut)  
*tsu-hi-tsu-gi* (Cherokee)  
 wild-oats

John Gerarde ([1597] 1975) called the European plants “throote wort or uvula woort, of the vertue it hath against the pain and swelling thereof.” Linnaeus ([1753] 1957) accepted the analogy and named the herbs *Uvularia*. He described American *U. perfoliata* and *U. sessilifolia*, and European *U. amplexifolia*. Subsequently, the European species was moved to *Streptopus* so *Uvularia* is now endemic to eastern North America. As currently circumscribed this is a genus of five species (Mabberley 1997). Four of these (*U. grandiflora*, *U. perfoliata*, *U. pudica*, *U. sessiliflora*) grow in the northeastern states (Fernald 1950). *Uvularia floridana* grows from South Carolina to Georgia, Florida, and Alabama (Radford et al. 1968).

*Uvularia perfoliata* and *U. sessiliflora* were eaten by the Cherokee; the leaves were boiled or fried with fat as greens (Hamel and Chiltoskey 1975, Moerman 1998). Manasseh Cutler wrote of *U. sessiliflora* in 1785 that “the young shoots may be eaten as asparagus. The roots are nutritious and are used in diet drinks” (Fernald et al. 1958, Coffey 1993). Porcher (1863) agreed, and wrote of both *U. perfoliata* and *U. sessiliflora*, “The roots are...edible when cooked, and the young shoots are a very good substitute for asparagus.” Yanovsky (1936) said indigenous people throughout the eastern states ate roots and shoots. Mostly, the plants are recorded as medicinal. The Cherokee made a medicine of *U. sessiliflora* roots to stop diarrhea, and as a poultice on boils (Hamel and Chiltoskey 1975). The Iroquois used *U. perfoliata* roots as cough medicine for children, to treat eye sores, and to help broken bones heal (Moerman 1998). They also used *U. sessiliflora* roots to purify the blood, and as a poultice to help heal broken bones. The Ojibwa used roots in hunting medicine (Moerman 1998).

In 1751, John Bartram called *U. perfoliata* “Uvulary,” and said, “It was formerly taken for a species of Solomon’s Seal, having smooth leaves like it; but the stalk grows through the leaf and the little yellowish flowers something resemble a Lilly; it grows about a foot high, the root is white, and spreads like a Crow’s foot; some people call it by that name for that reason. It is a good root for gathering and breaking a boil, and makes a fine salve for healing wounds and ulcers; it makes a fine maturing poultice” (Bartram in Coffey 1993).

Porcher (1863) wrote of both *U. perfoliata* and *U. sessiliflora*, “The roots of the different species are subacid and mucilaginous when fresh; and a decoction of them has been employed as a domestic remedy in sore mouth and in affections of the throat; also considered as alexipharmic in snake bites.”

## V

### *Vaccinium*

(Ancient name of bilberry, *V. myrtillis*; presumably, Linnaeus used the Latin *vaccinus*, of cows, as reflected in the Germanic folk-name *Kuhteke*; alternately, *vaccinus* may be a corruption of Greek *hyakinthos*, the color purple or dark red; related words may be Akkadian *bakkitu*, professional mourner; *bakku*, tearful, *bititi*, lamented)

***Vaccinium arboreum*** (treelike) *cafaknv copo-peleksv (cafaknv,*  
huckleberry, *copo,*

anus, *peleksv*, puckered, Creek)

farkleberry (probably a corruption of sparkleberry) gooseberry  
(properly a name for *Ribes*, USA) *hape'tka ha'yi* (Biloxi)

[tree-, winter-] huckleberry (huckle- is presumed to have been derived  
from hurtle-, or whortle-) hurt [hurtberry] (from ca. 1450 when it was  
applied to a European *Vaccinium*, but not combined with -berry until  
1542; etymology uncertain)

*osakohchi [wasakohchi]* (Alabama); *owessv [owisa]* (Muskogee)

sparkleberry (appearing in literature by 1891, presumably because of  
the shiny fruits)

whortleberry [hurtleberry] (whortle- [hurtle-] derived from whort-, in a  
southwestern England

***Vaccinium*.** *Vaccinium arboreum* (top left). From Sargent 1905. *Vaccinium corymbosum* (top right). From Britton and Brown 1897. *Vaccinium myrsinites* (lower left). Drawn by P.N.Honychurch. *Vaccinium stamineum* (lower right). From Britton and Brown 1897.

dialect, where the “w” is added, as in “whome” for “home” and “whole” for “hole,” dating from 1570s; originally applied to a European species, then extended to American plants) *yunlo* (Choctaw)

***Vaccinium corymbosum*** (having flowers in a corymb or flat-topped cluster)

*accoondews* (this may be the species mentioned in [1612] 1953 by Strachey, who said the fruits were “blue berries of the bignes of grapes very pleasant”; Powhatan, Virginia)

bilberry [billberry] (from Danish *böllebaer*, where *bölle* means ball or ball-shaped, and *baer* is fruit. *Bölle* is sometimes used alone to designate the species. Usually applied to *V. myrtillus*, a native to Eurasia where its fruits are used to make pies and other foods. Williams [1837] 1962 identified this species by the Old World name.)

giant whortleberry

high-bush blueberry [highbush blueberry]

*oksakohchi* (*oksak*, hickory, *ohchi*, to draw water, Choctaw); *okciskó* (*okcí*, juice, *ísko*, drinker, Koasati)

***Vaccinium darrowii*** (named for George McMillan Darrow, 1889–1983, who first recognized the species and brought it into cultivation at Beltsville, Maryland in 1940)

*cafaknv sopahvtke* (*cafaknv*, huckleberry, *sopahvtke*, gray, Creek)

Darrow's blueberry (a book name, Florida)

***Vaccinium myrsinites*** (resembling *Myrsine*)

*cafaknv* [*câ: faknâ, tsafuckina, caafakna, chafakana*] (Creek); *cafaknv Ivstuce* (little black huckleberry, Creek)

huckleberry (Florida)

*olake* [*olâkî, oluckee, olâká: pî*] (*olaki*, huckleberry, *api*, tree, Mikasuki)

shiny blueberry (Florida)

whortleberry (Williams [1837] 1962)

***Vaccinium stamineum*** (with prominent stamens)

[buck, deer, goose]-berry [berries]

*bleuet* [*bluet*] (blue one, Quebec)

[squaw]-huckleberry (USA)

whortleberry (Williams [1837] 1962)

Because *Vaccinium* has a circumboreal distribution, it has been used by people around the world (Mabberley 1997). Even the etymology of the generic name records long association with people. Moerman (1998) listed 16 species used across North America.

Five species are known to have been used in Florida, but surely another one, *V. tenellum*, was similarly valuable. At least the Algonquin and Iroquois used *V. corymbosum* (Yanovsky 1936, Moerman 1998). Maybe one of those is the unidentified species mentioned among the Alabama as medicinal (Swanton 1928a). Williams ([1837] 1962) called it “bilberry,” and that implies that the fruits were edible.

Oddly, Moerman (1998) does not mention *V. arboreum* or *V. stamineum*. At least among the Seminoles of Florida and Oklahoma, the value of the former is well documented. In Oklahoma, the roots of *owisa* are boiled and the infusion is used on someone who is “out of his head” and talking and behaving erratically. Deer are fond of berries and hunters often look for animals near stands of them (Howard 1984). From New England west to Minnesota and Wisconsin, indigenous tribes ate fruits of both *V. stamineum* and *V. corymbosum*.

Among the Florida Seminoles, Alice Snow recognized a species she called *cafaknv copo-peleksv*. Her description of it being taller than *cafaknv Ivstuce*, and growing on one stem with wider leaves certainly suggests *V. arboreum*, which extends into the Brighton Reservation region. She says the bigger berries are used for pies and jellies (Snow and Stans 2001), which is what people have used them for throughout its range. Farther north, decoctions of the leaves and bark of the roots were used to treat sore throat and diarrhea, and a drink made from fruits helped relieve chronic dysentery (Krochmal 1973). Surely the Seminoles, like the settlers, used the hard, brown, close-grained wood for tool handles (Small 1933).

Hogan (1978) listed *V. myrsinites* pollen from the Fort Center site on Lake Okeechobee, although it is likely that she used that species only because it was the common plant there. Regardless, *Vaccinium* has been associated with people in Florida since before the Europeans arrived. To the Seminoles on the Big Cypress and Brighton Reservations, this is the most important species. Sturtevant (1955) found them using it for “Sun Sickness” (eye disease, headache, high fever, diarrhea), “Hog Sickness” (unconsciousness), and during birth, death, and busk ceremonies (see *Pterocaulon*). Then and now the berries were eaten. Alice Snow makes medicine from *cafaknv*, which she considers “good for anything” (Snow and Stans 2001).

Farther north on the peninsula, *V. stamineum* is more common. South of Lake Okeechobee there are only a few restricted areas where it grows. To some people the fruits are unpalatable and supposed to be poisonous, but some individual plants are said to give delicious fruit (Fernald et al. 1958).

### *Vanilla*

(Philip Miller named this from the Spanish *vaina* or *vainilla*, referring to the cylindrical, sheathlike “pod,” actually fruit; the Spanish was based on Latin *vagina*, a sheath)

***Vanilla bar be llata*.** a. a. Upper part of plant, b. Flower, front view, lip in natural position, sepals and petals spread open. c. Lip, attached to column, in natural position, side view. d. Lip detached from column, spread open. *Drawn by Gordon W.Dillon.*  
From Correll and Correll 1982.

***Vanilla barbellata*** (little beard, in reference to the “hairs” on the labellum)

*bejuco de lombriz* (worm vine, Cuba, Dominican Republic);  
*lombricera* (wormer, Puerto Rico); worm-vine (Florida, Bahamas)

*liane couleuvre* (snake vine, Haiti)

*liane vers* (*liane*, twiner, *vers*, about, Haiti)

link vine (Bahamas)

***Vanilla phaeantha*** (gray flowers) leafy vanilla

In both Cuba and Hispaniola, these and other species of *Vanilla* are used in remedies against worms (Liogier 1974). Pods of *V. phaeantha* are sold as a substitute for cultivated vanilla (*V. planifolia*) (Hocking 1997).

### *Verbesina*

(Some say Linnaeus thought these had leaves resembling *Verbena*; others think the name was “metamorphosed” from that name; in either case, *Verbena* is an ancient Latin name given to a sacred plant)

***Verbesina virginica*.** From Britton and Brown 1898.

#### ***Verbesina virginica*** (from Virginia)

crown-beard [crownbeard] (“crown” from Middle English *coroune* or *crowne*, from Old French *cor one*, from Latin *corona*; first in English in the 12th century; “beard” refers to the pappus); white crown-beard (Missouri) *epte aape* [*iptá:pî*, *itutapi*, *ip'tápi*] (frost stem,

because the interiors of the stems freeze and the stems split open; *epte*, ice, *aapé*, stem or handle, Mikasuki); *hitotapî* (*hetute*, frost, *vpe*, stem, Creek)

frost-weed [frostweed]

*holshish okwa stikbe ishkwô* (“root water put in drink,” maybe from *hakshih*, root, *oka*, water, *shikoli*, bundle, *ishkwô*, drink, Choctaw)

Indian-tobacco

tickweed [tickweed] (maybe a host for ticks?)

Frostweed must be an ancient name for these plants. Even Steyermark (1963) mentioned that the water frozen in the stems produces “frost flowers.” He explained that these are “white, ribbonlike, fluted, and sometimes twisted ice formations...[which] result from the rise of the cell sap and moisture from the still active root into the dead and dry stems.”

Apparently, the first use of “frost-weed” in English was in 1866, for *Helianthemum canadense*. However, by 1856 the name “frost-wort” was used for *Cistus canadensis*. Both of those were considered medicinal, having tonic and astringent properties.

*Verbesina* is associated with medicines throughout its range in the Americas. An infusion of *V. virginica* roots was taken by the Choctaw to relieve fever (Bushnell 1909, Taylor 1940). The Chickasaw used it as a “deobstructant,” as a diuretic, for uterine problems, as a stimulant, and to treat venereal disease (Campbell 1951).

Sturtevant (1955) found the Seminoles using *epte aape* to treat “Bear Sickness” (fever, headache, thirst, constipation, blocked urination), “Fire Sickness” (fever, body aches), “Mist Sickness” (eye disease, fever, chills), and stomachache (root bark decoction). An emetic of root bark is also taken at funerals, at “doctor’s school,” and after the death of a patient.

Bennett (1997) found the Seminoles still using the herbs. The roots are scraped into water; the solution is taken orally and used to wash the patient to treat “night sweats,” fever, or hot flashes. This is considered a “cold medicine.” The plant also affords protection after lightning strikes, as people are vulnerable to “bad spirits” after lightning strikes.

*Verbesina helianthoides* (gravel-weed crownbeard, sunflower crownbeard) was called diabetes weed in the 1880s in Georgia (Hocking 1997). It was used as a diuretic to relieve edema and urinary problems (cystitis).

Morton (1981) also lists three other species. Those are used in Haiti and the Virgin Islands (*V. alata*, *V. gigantea*), Mexico (*V. gigantea*), and Costa Rica (*V. scabriuscula*). Both *V. alata* and *V. gigantea* are considered antispasmodics used to relieve stomachache and muscle strains, and are emetic, while *V. gigantea* is also used against toothache (Lewis and Elvin-Lewis 1977). *Verbesina scabriuscula* is used in healing baths. In the southwestern United States, *V. encelioides* (cowpen-daisy, *añil del muerto*) is used by the Hopi, Navajo, and Zuni; it too is emetic, and it is used to treat stomach and skin problems (Coffey 1993, Moerman 1998). Other species are used in Mexico, Venezuela, Guatemala, and Costa Rica (Hocking (1997).

### *Veronicastrum*

(“False Veronica”; based on *Veronica*, from *vera*, true, and *eicon*, image, from the early Christian legend picturing St. Veronica, wiping Christ’s face on the way to Calvary, with a handkerchief that received a miraculous “true image” of his features, and the *suffix-astrium*, resembling)

***Veronicastrum virginicum*.** From Britton and Brown 1897.

***Veronicastrum virginicum* (of Virginia)**

Beaumont's [Bowman's] root

black-root [blackroot] (Missouri)

Brinton's root (according to Rafinesque in 1826, named for a physician who used it in his practice)

[Cubeun's] Cubeno-root [-physic]; physic root

Culver's physic (used in print by 1858); Culver's root [Gulver's root, an error by Porcher 1863] (recorded in Massachusetts in 1716; according to Rafinesque, named for a Dr. Culver who used it in his practice; Millspaugh 1892 and Core 1967 said that the plant was introduced into England in 1714; however, the herb had been mentioned by Plukenet in 1696)

high veronica; tall veronica; *veronique de Virginie* (Virginia veronica, French)

*him* (from *hi-ni'-e*, toothache? Osage name according to homeopathic physician J.U.Lloyd, but the plant is not mentioned by Hunter [1823] 1973 or La Flesche 1932); Virginia-hini (maybe based on the Osage name)

*Leptandra* (from Greek *leptos*, slender, and *andros*, male, a generic name applied by Nuttall in 1818); *Leptandra-Wurzel* (Leptandra herb, German); *purple-Leptandra* (the purple form) oxadaddy (English?)

*quitel* (Delaware name according to homeopathic physician J.U.Lloyd)

*quitich* (according to Britten and Holland's *A Dictionary of English Plant-Names* of 1886, "quitich" is a "grass," but "in County Donegal [Scotland], every weed is so called")

tall speedwell ("speedwell," meaning "goodbye," is a generic common name for *Veronica*; it alludes to the rapid fall of the corollas if the spikes are picked; in use by 1578)

*virginischer Ehrenpreis* (Virginia honor-prize or speedwell, German)

whorly wort [whorlywort] (an allusion to the multiple leaves at each node along the stem)

Linnaeus ([1753] 1957) called these plants *Veronica virginica*, based on plants cultivated in Holland, Sweden, and herbarium specimens. Subsequently, Philipp Conrad Fabricius (1714–1774) created the generic name *Veronicastrum* in 1759. Nuttall did not realize that the herbs had a name and established the generic synonym *Leptandra* in 1818. Both the names *Veronica virginica* and *Leptandra virginica* were used in the older literature. It was not until 1917 that Oliver A. Farwell (1867–1944) created the name used today for this endemic North American species.

This herb grows from Massachusetts and Vermont to Manitoba and south to Florida, Mississippi, Louisiana, and eastern Texas (Fernald 1950). There is a sister species in eastern Asia (*V. sibirica*) that Millspaugh (1892) and other physicians considered the same as American plants. Although Czerepanov (1994) recognized other species in Asia, Mabberley (1997) thought there were only two.

The Cherokees used the root as a purgative and antiseptic. They applied the remedy to treat typhus and bilious fevers, induce sweating, as a tonic, and for inactive liver they mixed it with Indian physic (*Gillenia* spp.) and boneset (*Eupatorium perfoliatum*). The Cherokees also chewed the plant to relieve colic and drank a tea of it for backache (Hamel and Chiltoskey 1975). The Menomunis used *V. virginicum* as an emetic and physic, and a “reviver,” for purification when defiled by the touch of a bereaved person (Vogel 1970). The Meskwaki used the root to cure constipation and kidney stones, for ague, and as a medicine for women who were “weak” or in labor (Vogel 1970). The Ojibwa used a decoction of the crushed root as a cathartic, physic, and to clean scrofula sores caused by tuberculosis (Moerman 1998). The Senecas used the root as a cathartic (Vogel 1970). Other Iroquois considered it a treatment for chills and fever, diarrhea, rheumatism, as a physic, an emetic, a treatment for heart problems, and a “witch medicine” (Moerman 1998).

Probably because they considered the bowel to be the source of most maladies, European settlers in the New World were quick to adopt these plants as remedies. Cotton Mather wrote in 1716 to John Winthrop of New London, asking for some Culver’s root to treat his eldest daughter who had consumption. She died the next month after the remedy arrived, and Oliver Wendell Holmes opined, “all the sooner, I have little doubt, for this uncertain and violent drug, with which the meddlesome pedant tormented her” (Vogel 1970). André Michaux wrote on 11 Dec. 1795 at Kaskaskia, Illinois, that he was “confirmed once more in my opinion that the root of *Veronica Virginiana*...used as a decoction for a month, is effective for the cure of Venereal Disease” (Vogel 1970).

Porcher (1863) was more realistic than Michaux. He wrote: “The root is bitter and nauseous, yielding its active properties to boiling water. In the recent state [fresh] it is said to act violently, sometimes as a cathartic, and sometimes as an emetic. ...Under the name blackroot, Culver’s root, and the probably erroneous botanical name (*Leptandra alba*), the author of a work professing to describe the Indian mode of treating diseases, entitled the “Cherokee Physician,” recommends the plant as an efficient purge: ‘operating with mildness and certainty’; peculiarly adapted to typhoid and bilious fevers. Dose, a large teaspoonful of the root in a gill of boiling water, repeated in three hours. It is said to be also diaphoretic. The root may be given in any shape, and is thought to have a slow,

alterative action. An extract is also used in making cathartic pills by concentrating the decoction, and using starch or liquorice root powder; or a syrup is made by adding molasses or sugar. It is laxative in tablespoonful doses. A principle called leptandrine, from the *Leptandra*, is much used in the Western states. An emetic decoction is made by the vegetable practitioners with the *Leptandra* root: half a pound American ipecacuanha, or the Indian physic one pound, put into a gallon of water and boiled down to a pint, of which the dose is an ounce every twenty minutes till vomiting is induced; or two teaspoonfuls of the powder may be given in an ounce of boiling water, to be repeated.”

The drug was listed in the U.S. Pharmacopoeia under the name *Veronica* in 1820, and it remained there until 1840 (Vogel 1970). It was restored in 1860 under the name *Leptandra* and remained listed until 1916. It was in the National Formulary from 1916 to 1955. The dried roots and rhizomes were the parts used as a cathartic and emetic.

Hocking (1998) wrote that the herb had been used as a laxative, to treat rheumatism, as a cathartic, an emetic, a liver stimulant in hepatitis, a diaphoretic, a tonic, and applied to hemorrhoids. Foster and Duke (1990) warned that traditionally the dried root was the part used and that the fresh root was a violent laxative that was potentially toxic.

Roots and rhizomes of *V. virginicum* contain the bitter leptandrin (glycosidal amaroid), a glycoside resembling senegin, hormonal substances, resins, saponins, tannin, fatty oil sitosterol, and volatile oils (including esters of cinnamic acids) (Bown 1994, Hocking 1997). Duke et al. (2002) are guarded about the plants, noting that dried roots only are to be used. They give it a single plus—not as safe as coffee.

### *Viburnum*

(The classical Latin name; some say of doubtful meaning, others affirm it means “wayfaring tree”)

***Viburnum nudum*.** a. Branch with flowers, b. Flowers, c. Calyx and ovary, d. Branch with fruit, showing enlargement of leaves by fruiting time. Drawn by Vivian Frazier. From Correll and Correll 1972.

**ʔakí** *alyoká* (**ʔakí**, arrow, *alyoká*, arrow-wood; makings, Koasati); *mon'-ci hi* (*mon'-ci*, arrow, *hi*, plant, Osage) *korsved* (cross wood, Norwegian) *Schneeball* (snow ball, German) *viburno* (Italian, Spanish); *viburnum* (used in English by 1731); *viorne* (French)

***Viburnum acerifolium*** (maple-leaved)

*anib'* (Ojibwa)  
 arrow-wood (applied to several *Viburnum* spp. by 1848)  
 dockmackie (obscure; maybe from Gaelic *dogha*, meaning *Rumex*, and *meacan*, root, an allusion to medical use of the roots; by analogy, the carrot, *Daucus carota*, is "mackenboy," which was derived from Gaelic *meacan buidhe*, yellow root)

Guelder-rose (originally applied to *V. opulus*; named from *Guelders*, a town in Prussia on the Holland border)

laurestinus (usually applied to *V. tinus*; originally two Latin words, *laurus*, laurel, *tinus*, a plant)

maple-leaf [maple-leaved] viburnum (a book name)

possum-haw [possumhaw] (“possum” is a colloquial form of “opossum,” the American marsupial, *Didelphis virginiana*, alluding to the animal eating the fruits; “haw” is from Old English *haga*, hedge, akin to Dutch *haag*, German *hage*, Danish *have*, garden)

squash-berry

*viorne* (Quebec)

***Viburnum dentatum*** (toothed)

*conoská cobá* (*conoská*, heart, *cobá*, big, Koasati)

mealy-wood (Peter Kalm called this “mealy-tree” when he found it at Lorette, Quebec in 1749; in doing so, he was using a European name for *V. opulus* that was in use by 1706; probably the name was given to note the scaly buds of the European plant)

southern arrow-wood [arrowwood]

***Viburnum nudum*** (naked, from the definitely peduncled cyme)

[black, naked] alder

bilberry (of Norse origin, related to Danish *böllebaer*, from *bölle*, meaning unknown, *baer*, berry; originally applied to *Vaccinium myrtillus* ca. 1577, later to American plants)

[possum, Shawnee, swamp] haw [possumhaw] (“possum” because of the insipid fruits)

nannyberry [nanny-tree] haw (“nanny” perhaps elliptical for nanny-goat, a female goat, first applied to the animal by 1788; however, we must wonder if the term “nanny” here is not adapted from indigenous languages like Dakota where *V. lent ago* is known as *mna*, or *mna-ha* and *nan* in Omaha-Ponca)

southern wild-raisin

[smooth, naked] withe-rod [with-rod, with-wood] (“withe” or “wythe” is a piece of limber plant stem that is used for tying or binding, first used about A.D. 1000; the word was derived from Old English *wippe*, related to Old Frisian *withethe*, with cognates in other Germanic languages, and often applied to willows)

***Viburnum rufidulum*** (reddish)

*ʔakakcó ʔakí,* arrow, Koasati)

rusby black-haw [blackhaw, black haul]

*webasa’p* (hauls bone, Catawba)

Southern Europeans knew about these tall shrubs at least by the time of Virgil (70–19 B.C.), who wrote about *lenta viburna* (*lenta*, pliant, *viburna*, maybe from *via*, path). Later, the Romans also called them *lentagenem*. That pliant nature led to them being called *lantana* by English speakers by the 1200s, and much earlier for people speaking Romance languages.

Still, there is no doubt what these names meant because there are no native European *Lantana* (in the modern sense of Verbenaceae). Therefore, it is believed that Virgil applied the name *lenta viburna* to one or more of the European *Viburnum* (Adoxaceae). One of the common names for the genus is “arrow-wood.” Arrow shafts made of *V. lantana* accompanied the Neolithic “Iceman” found in the Alps (Mabberley 1997).

Perhaps John Gerarde in 1597 was simply translating the word *Viburnum* when he wrote that the shrubs were called “wayfarer’s-tree.” The OED (1971) noted that the name is an abbreviated form of “wayfaring man’s tree.” No further explanation is given, but that surely came into use because of the utility of the plants. Two of the best-known European species are *V. opulus* and *V. tinus*; the first is famous for its poisonous raw berries that become edible when cooked (Bown 1995). Both yield notable herbal medicines (Bown 1995, Hocking 1997).

By the time the New World was discovered, settlers were acquainted with European species. Exploration of the eastern coast revealed more species, and Linnaeus named the Florida plants in 1753. Three species were based on John Clayton’s 1730s collections and originally discussed by Jan Gronovius in his *Flora Virginica*. Linnaeus knew 8 species, and there are now 150 recognized in temperate Eurasia and North America (Mabberley 1997). Kartesz (1994) accepted 21 species in North America, but that includes *V. lantana*, *V. sieboldii*, and *V. tinus*, which have become naturalized from the Old World.

Many of the species were recorded to make arrow shafts. *Viburnum acerifolium*, *V. dentatum*, and *V. rufidulum* are among the Florida species recorded (Vines 1977, Kimball 1994).

There are direct records of people eating the fruits from the northeastern states to the Great Plains (Gilmore 1919, Hedrick 1919, Moerman 1998). For example, fruits of *V. nudum* were eaten by Abenaki and Algonquin; Missouri River people ate *V. lentago*. However, drupes probably were more important in the past. *Viburnum acerifolium* was *anib’* to the Ojibwa. To the Missouri River people *V. lentago* was *mna hu* (Dakota), *nan shaman* (Omaha-Ponca), *wuwu* (Winnebago), and *akiwasas* (Pawnee). The North American form of *V. opulus* was known to the Cree as *nipinminan* (*nipin*, summer, *minan*, berry). That name was corrupted by settlers to *pembina*, which became the name of a river. The Ojibwa called the river *nepinminan sipi* (summer-berry river). Later, Pembina became the name of a mountain, town, and county in the northeastern corner of North Dakota. The Pembina River runs from south-central Manitoba into North Dakota, where it then flows across the northern part of Pembina County and empties into the Red River. Englishman John Lindley called fruits of *V. opulus* “a miserable food for savage nations” in 1846. Perhaps because of the thin-fleshed fruits, most tribes had abandoned them in favor of larger and more flavorful fruits from Europe by the time people began keeping records (Hedrick 1919).

The Delaware, Ojibwa, and Omaha mixed bark as part of a *kinnikinnick* (mixture, Algonquin) for smoking. Since the tribes were historically using *Nicotiana rusticum*, doubtless they were adding the *Viburnum* to dilute the strong tobacco taste.

By far the most important use among indigenous tribes was in medicine as an antispasmodic. Both *V. opulus* and *V. prunifolium* are known to contain scopoletin, a coumarin glycoside that has a sedative effect, especially on the uterus. Lewis and Elvin-Lewis (1977) indicated that coumarin glycosides are uncommon in plants, and it is suspected that most *Viburnum* have them. *Viburnum prunifolium* also contains salicin, and Bown (1995) recommended its use with *V. opulus*. The Cherokee, Iroquois, Menomini, and Ojibwa made an infusion of *V. acerifolium* to relieve cramps and colic (Hamel and Chiltoskey 1975, Moerman 1998). Iroquois women took a decoction of *V. dentatum* twigs as a contraceptive and made a poultice for swollen legs after childbirth. The Cherokee used *V. nudum* to prevent spasms.

Other medicines are related to these antispasmodic uses. The Iroquois took an infusion of *V. acerifolium* as a diuretic; they also drank an infusion and applied a poultice for pain they considered caused by witchcraft. Since *V. dentatum* is used as an adulterant for *V. prunifolium*, it too probably was used as a diuretic (Hocking 1997). Both *V. acerifolium* and *V. nudum* were made into tonics by the Cherokee (Hamel and Chiltoskey 1975).

The coumarin glycosides or chemicals called “viburnin” may be responsible for the other applications (Hocking 1997). The Cherokee used the root bark of *V. acerifolium* and *V. nudum* as a diaphoretic, febrifuge (including malaria), and treated sore tongues with it (Hamel and Chiltoskey 1975). The Menomini treated cramps and colic with a decoction of inner bark (King 1984); The Ojibwa made it into an emetic (Densmore 1928, Moerman 1998).

### *Vicia*

(The classical Latin name, used by Varro, 116–27 B.C.; Quattrocchi (1999) thought it came from *vici*, I conquer, based on *vincere*, to be victorious; according to Saint Isidore, archbishop of Seville, “*herba vicia, id est victor ialis*” the herb *vicia*, it is victorious)

***Vicia caroliniana*.** From Britton and Brown 1897.

***Vicia sativa*** (the common European species; not in Florida)

*arvejas* (Spanish, 1557; from Latin *arvilia*, probably originally the same as what is now *V. ervilia*, European bitter vetch)

*gall-pheasair* (*gall*, stone, *pheasair*, peas, Gaelic)

*ketsach* (Hebrew, de Candolle [1886] 1959)

vetch (from Old French *vecce*, *vesse*, which was taken from Latin *vicia*); *bicio* (Fuchs 1542); *bikion* (Greek, Galen A.D. 129-?200); fetch (John Gerarde [1597] 1975); *fiatail* [*fiatghal*] (Gaelic); fiche (Turner [1548] 1965), *veccia* (Italian by 1551); *vesce* (French by 1575); *vesse* (French by 1550); *viccia* (modern Italian); *vitsen* (Dutch 1549); *Wicke* [*Wicken*] (German, Fuchs 1542)

***Vicia caroliniana*** (of Carolina)

*altsa'sti* (a wreath for the head, Cherokee)

*vesce* (Quebec)

[Carolina, pale, woody] vetch

Not long ago my wife and I ate dinner with our friend Valeria Volin, who is from Padua in northern Italy. She was serving a “special” Italian dish that my wife and I had never eaten. This specialty consisted of raw fava beans (*Vicia faba*), sweet fresh figs (*Ficus carica*), and cheese. As I peeled the beans and munched them with the figs and cheese, I could not help thinking of the people in the Mediterranean who had to balance such a meal between too little and too much. Too little and they ran the risk of getting malaria; too much and they stood a good chance of dying.

Those people, largely of African black, Greek, and Italian heritage, have inherited a red blood cell enzyme deficiency called “favism” (glucose-6-phosphate dehydrogenase, often abbreviated G-6-DP) (Perkins and Payne 1978, Desowitz 1987, Foster and Caras 1994, Duke et al. 2002). When these people are exposed to certain substances, they develop intravascular hemolysis where the red blood cells disrupt. The sulfonamides and the antimalarial drug primaquine are two of the other chemicals causing that disruption. Yet, the most powerful hemolytic inducer is the fava bean. Those beans eaten by sensitive individuals can be fatal. Even inhaling the pollen may induce favism.

People long ago made the association between the dangers of fava beans and potential death (de Cleene and Lejeune 2002). They elected to continue eating the beans because they liked them, and another realization—eating favas lessens their chance of developing malaria. They did not know it, but the partial anemia is the reason for reduced risk. Favas remain so popular that they are sold fresh in some communities in the southern United States. Farther north, beans are sold canned and frozen.

Linnaeus gave us the scientific name *V. faba*, continuing the use of Gaspar Bauhin's *Pinax* from 1623. The plant producing the edible seed was known in classical Latin as *faba* and *cyamos* in Greek. Fuchs (1542) still called it *cyamo*, but included the synonym *faba*. William Turner's *Her ball* of 1551 called it “beane,” but John Gerarde said “great garden bean” in 1597. We now associate the word “bean” with the legume *Phaseolus*, a native of the New World. However, that is a recent application. The word “bean” comes from Old Teutonic *béan* and appeared in Anglo-Saxon about A.D. 1000, and two Germanic cognates are *boon* (Dutch) and *Bonhe* (German). The same root probably gave rise to the Gaelic *pònaire*. The “bean” of pre-Columbian Europe was *V. faba*.

Other English names for these seeds are horse-bean and broad-bean. The former came into use with a belief (among the rich) that they were fit to eat only by horses. Poor people knew better, and the proverbial expression of “beans and bacon” meant *V. faba* well into the 20th century. Broad-bean came into use to distinguish *Vicia* from *Phaseolus* after the New World plant was brought to Europe. Although Turner called *Phaseolus* “kidney bean” in 1548, people confused broad-beans and kidney beans into the 1770s. Bernard Romans ([1775] 1961), for example, used the expression “beans and pease” in several places to indicate native American *Phaseolus*.

Herbalists in Europe usually mentioned only two *Vicia* (*V. faba* and *V. sativa*). Linnaeus ([1753] 1957) listed 17, but there are 54 native to Europe (*Flora Europaea* 2003). In total, there are 140 species in the genus, mostly in northern temperate regions (Mabberley 1997). There are 31 species in North America (Kartesz 1994), but several of them are naturalized from elsewhere in the world.

The Florida species that has a record of use by the Cherokee was not discovered until the late 1780s. Thomas Walter, a British-American planter living in Charleston, named *V. caroliniana* in his *Flora Caroliniana* published in 1788.

Comparatively few *Vicia* have been used by people, partly because they are so poisonous. Many contain both cyanogenic glycosides and lectinic compounds (*V. cracca* contains alpha-D-galpNAc; *V. graminea* has beta-D-Galp, anti-N [RBC site]), which render them dangerously toxic (Lewis and Elvin-Lewis 1977). Millspaugh (1892), for example, noted that seeds of *V. ervilla* (European bitter vetch) were a virulent poison to humans and horses. No reports are known of poisoning by *V. caroliniana* (Perkins and Payne 1978), but *V. sativa* elsewhere in North America has caused problems (Turner and Szczawinski 1991).

Europeans use some species as fodder for domestic stock (de Candolle [1886] 1959, Meyer et al. 1999). Both *V. ervilia* and *V. sativa* have long histories. De Candolle ([1886] 1959) noted that Greeks still were cultivating *V. ervilia* in his time. Seeds of *V. ervilia* are known from Turkey dating back to the 6th and 7th millennia B.C. Zohary (1982) also cited several Neolithic and Bronze Age sites with *V. sativa* in the Near East and Europe. This is still a minor crop in the Mediterranean basin and the Near East, although the seeds are poisonous. Once soaked in water, seeds are eaten, but only during famine (Zohary 1982).

*Vicia sativa* was said by Cato (234–149 B.C.) to have been cultivated for both seed and fodder by the Romans (de Candolle [1886] 1959). Zohary (1982) clarified that the seeds were used to propagate the plants, and not for human food.

Among indigenous American tribes, records have been found for use of only seven or eight species. Two of those, *V. faba* and *V. sativa*, are Old World introductions. Maybe they learned uses of those alien species from Europeans, because in England a decoction of vetches in water was given by nurses to “expel” smallpox and measles (Lightfoot 1777 in Vickery 1995). However, they are just as likely to have discovered uses on their own. In the eastern states, the Cherokee, Iroquois, and Rappahannock are known to use *Vicia* as medicine. The Iroquois used both *V. americana* and *V. sativa*; the Rappahannock used only *V. villosa* (Moerman 1998).

The Cherokee used *V. caroliniana* for several purposes, and they considered it one of their most valuable medicinal herbs. Mooney (1885–1886) was the first to record most of these applications, and he has largely been copied by Hamel and Chiltoskey (1975).

Decoctions were drunk for dyspepsia and for pains in the back, rubbed on the stomach for cramps, and used to treat rheumatism. The same medicine was also important in treatment of the disease known as *unnagei*, in which one side of the body develops black spots and partial paralysis. To treat that problem, the affected area was scratched, and the liquid applied to the scarified region. The Cherokee also took an infusion as an emetic (Taylor 1940).

Ballgames were an important element in south-eastern living, and the Cherokee were addicted to them like many other tribes. *Altsa'sti* was a crucial medicine for players. Their limbs were scratched and the infusion rubbed on to render their muscles tough (Mooney 1885–1886). Hamel and Chiltoskey (1975) found a variation where an infusion of *altsa'sti* was not used alone. A compound mixture was made with Virginia pipe (mistake for Indian pipe, *Monotropa uniflora*?) and sweet apple (*Malus pumila*, introduced) as a drink to improve ballplayers' wind during the game.

### *Vigna*

(Dedicated to Dominico Vigna, Italian scientist of the 17th century)

*Vigna luteola* (yellow, the flowers)

*bejuco [frijol] marullero* (sea [bean] vine; *marullero* from *mar*, ocean, and *barullo*, confusion, Venezuela)

*caraota de monte* (wild *carao*; a *carao* is a tree legume)

Nicholas von Jacquin called this twining legume *Dolichos luteolus* in 1771, naming it from plants cultivated in Vienna. It was not until 1859 when George Bentham moved the species to *Vigna*, a genus created in 1824 by Italian botanist C. Gaetano Savi (1769–1844). This species is thought to be native to the New World, but it has been overshadowed by its cultivated relative *V. unguiculata*, the cow-pea, better known as black-eyed pea. That plant was brought into cultivation in Ethiopia and subsequently spread around the world (Simpson and Conner-Ogorzaly 1995). The genus has about 150 species spread through the tropics, especially the Old World (Mabberley 1997).

John Small (1933) knew these twiners from Florida to Texas, and north to North Carolina, and from the Caribbean, Mexico, Central, and South America. For a long time, people thought the proper name was *V. repens*, and older literature uses that epithet.

In spite of the wide distribution, uses have been found only in two disjunct places. A decoction of the plant is used to treat coughs and colds in the Virgin Islands (Morton 1981). Balick et al. (2000) also found it being used in Belize, but gave no details.

***Vigna luteola*.** a. Flowering and fruiting branch, b. Flower, side view. c. Flower, longitudinally dissected, d. Standard, e. Wing. f. Keel. g. Pistil, h. Floral diagram, i. Fruit. *Drawn by Priscilla Fawcett.* From Correll and Correll 1982.

*caupi de monte* (wild cow pea, Netherland Antilles); hairy-pod cow-pea [hairypod cowpea]; *waakimbala* (*waaka'*, cow, *im*, its, *bala*, bean, Chickasaw; probably belongs here)

*frijol cimarrón* [*de arena, de cabra*] (wild [sand, goat] bean, Cuba); *frijol de monte* (wild bean, Mexico); *frijol de playa* (beach bean, Honduras); *frijol silvestre* (wild bean, Puerto Rico)

goat wiss (wiss=vine, Virgin Islands)

*pois jaune* [*pigeon, zombi*] (yellow [pigeon, zombi] bean, Guadeloupe, Martinique)

*porotillo* (based on *poroto*, bean, meaning little bean, Spanish)

sea bean (Belize)

wild pea (Virgin Islands)

yellow vigna (a book name, Bahamas)

## *Viola*

(The classical Latin name for the violet; akin to Akkadian *asu*, and Hebrew *js*, to grow, Akkadian, *isum*, plant)

*amor-perfeito* (perfect-love, Portuguese)

*bròg na cubhaig* [*spòg na cubhaig*] (*bròg* or *spòg*, talon, *na*, of the, *cubhair*, cooper, Gaelic)

*fail chuach* [*dail chuach*] (*dail*, field, *fail*, wreath, *chuach*, plait or drinking cup, Gaelic); *sail chuach* (*sail*, willow, *chuach*, drinking cup, Gaelic)

*goirmean-searradh* (*goirmean*, indigo, *searradh*, cutting, Gaelic)

pansy (“pansy” was derived ca. 1500 from French *pensée*, thought; originally applied to European *V. tricolor*; perhaps the first suggestion of this use came in 1536 when Ruellius published *De natura stirpium* [On the Nature of Things], where he wrote “*Violae inodoraе genus esse putaverim quam vulgus gallicus penseam vocat*” [This is the odorless violet genus that is said to be commonly called *thought* in France]); *pensée* (French)

*Stiefmütterchen* (little stepmother, German)

violet (“violet” diminutive of Latin *viola*, derived in English from French *violette*; in English ca. 1330, and applied to the rayless kinds according to Mabberley 1997); *fiol* (from Latin *viola*, Norwegian); *Veilchen* (*veil*, violet, *-chen*, little, German); *viola* (Italian, Portuguese); *violeta* (Spanish, Portuguese); *violette* (French); *viooltje*

***Viola*.** *Viola conspersa* (left). *Viola sororia* (right). Both from Russell 1965.

[*violetje(s)*, *violet ten*] (Dutch); *vion* [*ion*, *io*] (Greek, cf. Russell 1965)  
*xtha-çka tsu-hu* (*xtha*, flower, *çka*, white, *tu-hu*, blue?, Osage)

***Viola bicolor*** (two-colored)

cupid's-delight (the same idea as the British name "love-in-idleness")  
 field daisy ("daisy" is usually applied to *Bellis perennis*, Asteraceae)  
 field pansy ("pansy" was derived ca. 1500 from French *pensée*,  
 thought)

heart's-ease [heartsease] (first recorded in Chaucer's *Clerk's Tales* in  
 the 1400s, where he wrote, "And wisly bringe hem alle in hartes eese";  
 the origin is uncertain, but the sense is tranquillity or peace of mind,  
 England)

Johnny-jump-up ("Johnny" [Johnnie] is a contemptuous nickname  
 given to Englishmen in the Mediterranean, and to Confederate soldiers  
 during the Civil War)

kiss-me-at-the-garden-gate (England)

love-in-idleness (England)

three-faces-under-a-hood (from 1548, England) wild pansy

***Viola conspersa*** (sprinkled, from the dotted lower leaf surface)

American dog-violet (the "dog-violet" of Europe is *V. canina*; so  
 named because it lacks scent; see Scott 1995)

***Viola sororia*** (sisterly, resembling other species)

bayou violet ("bayou" is a variant of the Choctaw word *bayok*,  
 meaning marshy branches of rivers and lakes; in use by 1763)

chicken-fights (Maryland); fighting cocks; *akankittibi'chi'* (*akanka'*,  
 chicken, *ittibichi'*, to make fight, Chickasaw); *dinda'skwate'ski* (they pull  
 each other's heads off, Cherokee)

Confederate violet (an allusion to the name Johnny-jump-up)

Johnny-jump-up[-and-kiss-me]

long-stemmed purple violet

rooster-hoods [roosters] (North Carolina)

sister violet (a "scholarly" translation without consulting people who  
 use common names)

[blue prairie, common blue, downy blue, hooded blue, meadow] violet

What could the violet and the peacock moth possibly have in common? Both were  
 dedicated to Io, the beautiful Greek priestess. The violet in Latin is *Viola*, which is related  
 to the Greek *Vion*, a variant of *Io*. The moth is *Automeris io*, named by Philipp Conrad  
 Fabricius (1714–1774) to honor that goddess—or perhaps to warn of her dangers as the  
 larvae are covered with stinging hairs.

According to Greek legend, Zeus was enamored of Io and seduced her. That made his  
 wife Hera furious, and to protect Io he transformed her into a white heifer. Io wept  
 because of the coarse grass that she was forced to eat. One version of the story is that

Zeus changed her tears into a sweet-smelling, dainty violet (*V. odorata*) as a special food (Lehner and Lehner 1960, Ward 1999).

Violets also figure prominently in the histories of Romans, Middle Eastern Muslims, and Napoleon Bonaparte. Romans drank violet-flavored wine and spent so much time cultivating the herb that Horace (65–8 B.C.) criticized them for spending more time on *Viola* than their olives (*Olea europaea*). Muslims extol the violet by saying, “The excellence of the violet is as the excellence of Islam above all other religions.” Napoleon was nicknamed the *Caporal Violette*, and he used either that or *Père la Violette* as a *nom de plume*. He died wearing a locket of violets taken from his wife Josephine’s grave (Bown 1995, Ward 1999).

There are 91 species of violet in Europe (Mabberley 1997), and the genus has been cultivated since 400 B.C. in Attica in eastern Greece (Mabberley 1997). *Viola odorata* has not only been used to flavor wine, but also in flavoring other materials, food (crystallized), and in scent making. Its fragrance still is used in creams, salves, soaps, oils, and shampoos (Lewis and Elvin-Lewis 1977). The main aromatic in *V. odorata* is ionone, and its synthesis in 1893 caused a dramatic decline in violet cultivation.

Newcomers to the New World were not surprised to find violets here. Strachey ([1612] 1953) included violets among the “many herbes in the Spring-tyme are Comonly dispersed throughout the woods good for broathes and sallets.” Kartesz (1993) listed 119 species, including numerous hybrids. Most of these were discovered comparatively recently, and Linnaeus ([1753] 1957) knew only 19 species in the world—he knew none of Florida’s species. Indeed, the Florida violets were described between 1809 and 1823.

Steyermark (1963) found the game called “Hens and Roosters” being played in the Ozarks. There they used *V. pedata*, and the “roosters” were the bicolored flowers, while the “hens” were uniformly colored. One person holds a rooster flower and another a hen. These are hooked together and the first person to pull off the other’s flower is the winner.

Coffey (1993) was under the impression that this was an invention of southeastern settlers, probably because of the names “fight rooster,” “fighting cocks,” or “chicken fight.” He found that people in the South used *V. sororia* instead of *V. pedata* (Coffey 1993). Moreover, ask anyone in the South who remembers the game, and they will tell you that it is a purely European-American game.

However, people from the Cherokee to the Omaha may have played the game before Europeans arrived in the New World (Mooney 1885–1886, Gilmore 1919). The Cherokee name recorded by *dinda’skwate’ski* (they pull each other’s heads off) clearly describes the game (Mooney 1885–1886). Gilmore (1919) voices no opinion, but comments that the game was popular among Omaha boys. It seems likely that the indigenous tribes invented the game and taught it to settlers. No records were found of Old World people playing it before the 1500s.

All three of Florida’s violets were used by indigenous people, and Moerman (1998) lists 14 other species used by different tribes. Although no records have been found of indigenous people eating the violet, that seems likely. Stephen Elliott (1771–1830), in his *A Sketch of the Botany of South Carolina and Georgia*, published between 1821 and 1824, treated all the palmately dissected leaf violets as “*V. esculenta*” and said, “This Violet is very mucilaginous and much used by negroes in their soup.” Later, Porcher (1863) called it “wild okra” and said that the blue violets were used in making soup during wartime. Only the leaves are used in the soups because the roots are emetic.

Fernald et al. (1958) wrote, “probably any of the ‘blue’ violets might be used” in soups. Kindscher (1987) added that some are more palatable than others. Zennie and Ogzewell (1977) found that the basal leaves of *V. papilionacea* have more vitamin A and C than any of 17 wild edible plants studied in Ohio and Kentucky. That report spawned the assumption that all violets have similar quantities of vitamins.

Most of the uses by indigenous people were in medicines. The Cherokee made a poultice of *V. bicolor* or *V. sororia* leaves for headache, took an infusion for dysentery, colds, and coughs, applied a poultice to boils, and considered it a spring tonic (for the blood) (Hamel and Chiltoskey 1975). An infusion of the roots was used as an insecticide to soak corn kernels before planting. The Seminoles in 1919 made a tea of some species to treat kidney trouble (von Reis and Lipp 1982). The Ojibwa made tea of *V. canadensis* for bladder pains and to treat heart pains (Vogel 1970). They used *V. conspersa* for heart trouble (King 1984). The Potawatomi also used *V. pubescens* to treat heart pains (Smith 1933, Vogel 1970). Those uses by northern tribes for heart remedies are reminiscent of the old European name “heart’s ease,” and Vickery (1995) found that application still practiced in England.

By far the most common utilization in Europe was for skin problems, and the Cherokee also used the plants for that. Porcher (1863) noted that violets were good for ulcers and other skin problems, and gave a formula for creating the remedy. Foster and Duke (1990) said that experiments with rats confirm efficacy for skin eruptions. Bown (1995) added that violets were being checked in England for use against skin cancer and childhood eczema.

The compounds that are used to treat skin problems are taken from the roots. Those known are saponins, and they may be toxic in large doses (Foster and Duke 1990). Moreover, rhizomes and seeds cause severe gastroenteritis, nervousness, and respiratory and circulatory depression in large doses (Lewis and Elvin-Lewis 1977).

### ***Vitis*: Grapes**

(To bend, plat, or weave, Latin)

***Vitis rotundifolia.*** Drawn by  
*P.N.Honychurch.*

Use of the fruit of *Vitis* is older than the history of any culture. At the time of contact with the New World, Europeans had a long, deep involvement with *Vitis*. The histories of both the name of the fruit and the plant are deeply rooted in the Eurasian languages. One example is Aesop's fable of the "Fox and the Grapes."

To the Greeks, the unripe fruit is *omphelos* or *omphax*, a dried fruit (raisin) is *astaphis*, and the plant *tamnus* (Brown 1954). In Hebrew, the plant is *gefen*, a vineyard is *her em*, and *anavim* is grape (Zohary 1982). In Egyptian Arabic, the plant and grapes are *'inab*, and grapes are *zibib* (Manniche 1989).

Our English word "grape" came into the language about A.D. 1290. The *South English Legendary* or *Lives of Saints* of that year included the sentence, "A luytel foul...brochte a gret bouch Fol of grapus swyte rede" (a little fow...brought a great bunch full of sweet red grapes). Before 1290, the word was *krappen* (Teutonic), *krappa* (Old High German), and *grap*, *grappe* (Old French), all meaning a hook. Presumably, the hook was the one used to harvest fruit from the vine. These words are related to *grappare* (Italian), to seize, and *grappa*, a hook, in Italian, Spanish, and Portuguese, but they use a different word for the fruit.

*Uva* (Italian, Spanish) and *uba* (Portuguese) are based on Latin *uva*. However, speakers of Latin distinguished between *uva* and *acinus*, *atrusca*, *bannanica*, *bumastus*, *irtiola*, *sircula*, *spionia*, *sticula*, and *talpona*. Those varietal names have not come into English, but *acinus* became *acino* (grape) in Italian. "Raisin" in French and English is based on Latin *racinus*, a bunch of grapes, although its meaning in English as dried fruit

has deviated to the point that they hardly seem related. German has retained the idea of the bunch of grapes with *Traube*, which means either raceme or grape.

“Vine” in all English dialects except American specifically indicates *Vitis vinifera*—the vine (Austin 1994). Americans have expanded the word to mean all creeping, climbing, or twining plants. The Latin *vitis* was retained more nearly in original form in *vigne* (French) and *vid* (Spanish). A synonym of *vid* is *parra*, from a different source. Gaelic speakers had other names, including *fionan* and *muin* (the 11th letter of their alphabet).

Europeans found many grapes in the New World, all different from those they knew at home. Between 1570 and 1577 Francisco Hernández recorded that the Náhuatl name of grapes in Mexico was *xocomecatli* (sour rope) or *ceual-chilchiltic* (cool and red). The Zapotec say *bicholi* or *yaga-bicholi* (*yaga*, tree, *bicholi*, grape).

The most widespread species in southeastern North America is *V. cinerea*, known as graybark or pigeon grape. That plant also is known as the *hastanhanka* (Dakota), *chan wiyape* (*chan*, tree, *wiyape*, twiner, Teton Dakota), *hazi-hi* (grapevine, Omaha-Ponca), *hapsintsh* (Winnebago), and *kisúts* (Pawnee). Probably, this is what the Cherokee called *uhnasuga*, and their relatives the *ojinquisere* (Onondaga). Delaware said *wisachgim*, and farther west, the Potawatomi called them *siwnwen*. To the Shawnee it is *teatepawtaquey* (Edgar 1891). Although their word is generic, the Yuchi called them *cá*.

To the Muskogee of Oklahoma *V. cinerea* is **pułko** [pv'rko]. The Creeks

of Florida say **empułko** (*wotko*, raccoon,

**empułko**, its grape), which is the same as *shaawe*

**embałbi** (Mikasuki). **Sawimbałka**

(Alabama), **imbałká** (Koasati), and *shawimpakki* (Chickasaw) have the same meaning. Maybe the Tunica name *yi'sihe'sani* (*yi'si*, raccoon, *he'sani*, vine) belongs here.

The Miccosukee name for *V. shuttleworthii* is almost the same as for *V. cinerea*, but

shortened. Spellings include **bałbi**, *bokbe*, *balbî*, and *cokasî*:

(Sturtevant 1955, Snow and Stans 2001). The name **bałbe** is pronounced

“**puł-be**,” and is cognate with the Creek word

*paʔko* [pvrko, párko], which is pronounced  
 “puʔ-go.” This grape is also called *paʔko*  
*ʔako* [pvrko rako] (big grape, Creek). Alabama speakers use the cognate  
*baʔka*, and Koasati *baʔká*. English speakers say summer  
 grape or Calusa [Caloosa] grape.

The other prominent species in the southeastern United States is *V. rotundifolia*, called the muscadine, southern fox grape, bullace, and scuppernong grape. “Muscadine” may have come from Portuguese *muscat*, which is cognate to Italian *muscato*. Both words came from Latin *muscatius*, having the flavor of musk. The word was in English as “muskadyne” by 1541. Muskatel is a strong sweet wine made from the muscate grape, and is *moscadello* or *moscatello* in Italian. “Bullace” is from Old French *beloce*, and denotes a plum, *Prunus*×*domestica* ssp. *insititia*. *Vitis rotundifolia* is the wild type from which people selected the cultivated scuppernong grape. That cultivar is said to be named for a river in North Carolina. Core (1967) says both fruit and locality are based on the indigenous word *askuponnong* (probably Algonquian). For those who have not tasted this giant-fruited cultivar, the fruits are more like plums than grapes, very different from the tart wild forms.

The Cherokee name for *V. rotundifolia* is *telu'lati* [qualusi] or *oonee tayluhn'dee*. Siebert (1975) thought the Powhatan name *wapapemins*, recorded by Strachey in [1612] 1953 as *wapapamindgas*, belonged here. The Powhatan word is composed of /\**wa-p-*/, white, /\**-a-pye-*/, vine, and /\**-eminsy-*/, drupe-bearing bush (Siebert 1975). Cognate is Fox *kiwapyehi*, creeping vine. Perhaps the Powhatan words *marakimmins* (grapes) and *metucsmarakimins* (bunch of grapes) written by Strachey are also cognates. Siouan-speaking Biloxi said *maktcuhi'* for the fruit, and *maktcuhi pan him* (*maktcuhi'*, grape, *pan him*, vine), Ofo said *on'ho'mofthu'* for the fruit and the plant was *anthu'hi fte' pi* (*anthu'hi*, creeper), while the Tunica called the fruit *so'su*, and the Atakapa *hila'n̄ wol te'i* (*hila'n̄*, buzzard's, *wol*, eye, *te'i*, vine).

According to Snow and Stans (2001), the Mikasuki say *chokooche*. That is the same word that Sturtevant (1955) recorded as *cóko:cí* (little grape, Mikasuki), and others spelled *chokoche*, *cokooci*, *chuko aske*, *tcokotci*, and *tsuk-ko-chee*. The Creek cognates are *culoswuce* [*colo:skocí*, *chukochet*, *chalushwa*, *so-losh-ka*, *chu-los-sho-a-kee*] (little muscadine), and Muskogee *culoswv* [*colóswv*]. In Alabama, the modern name is *chokkapihchi* (*chokko*, grape, *apihchi*, body), and in Koasati *cokkó*. The Choctaw called the vines simply *panki*, *paki vpi* (grape vine or stem), or *suko*. This also may be what they call *pankachuñsi*.

At first, it does not seem that the Muskogean words for grapes are closely related. However, closer examination suggests that they are all cognates. The sound of the “p” in Creek is unaspirated, unlike the aspirated letter in English. Because of the unaspirated

nature, the Creek “p” sounds to English speakers as though it were halfway between “p” and “b” (Martin and Mauldin 2000). Thus, the Muskogean words with either of these letters are closer in sound than they appear when written. Clearly, Alabama

*baɬka* is cognate with Mikasuki *baɬbe*, and both words are cognate with Muskogee *puɬko*. Similarly, Alabama *baɬka* is cognate with Chickasaw *pakki*, which in turn is cognate with *panhki*.

All of these words are used to denote the Florida or graybark grape, *V. cinerea*, however, their application does not seem to be confined to that species. For example, the

Calusa grape, *V. shuttleworthii*, is called *baɬka* (Alabama), *baɬbi* [*bathbi*, *bokbe*, *balbi*] (Mikasuki), or *puɬko* [*páɬko*, *paɬko*] (Creek).

It is the Muscadine grape, *V. rotundifolia*, that has the most distinctive names in Muskogean. Probably that is because this is the most characteristic species in the southeast. The Calusa grape is unique in that it has no pubescence on the leaves, and the fruits are smaller and thicker skinned than other grapes. Also, as pointed out by Seminole Alice Snow (Snow and Stans 2001), the “green leaves have little points on them and ragged edges [dentate margins] and are almost heart shaped [subcordate].”

The Muskogean name for the Calusa grape is *culosw* [*coló:swv*] (Creek), but it is usually given with the diminutive ending as *culoswuce* (*culosw*, grape, *oce*, small). The Mikasuki *chokooche* [*cokasí:*] means the same.

Sturtevant (1955) said that Mikasuki word was equivalent to Creek *parkofaká*

[*paɬkofaka*] (from *puɬko*, grape, *fɨkv*, vine, grape vine). The Mikasuki stem word *cóko* [*choko*] is cognate with *chokko* (Alabama), and Choctaw [and Chickasaw?] *sokko*. Those words are also the source of the Mobilian Jargon name *sok(k)o*. Drechsel (1997:66) suggests that the names are probably derived from the word thick, *sok(k)o*, in reference to the skin of the fruit. The Choctaw apparently also use the word *paki* for fruits in this species, and that word is the same as *panhki*, their word for *V. aestivalis*.

Everyone who knows grapes, from the extinct Apalachee to Timucua and Calusa to the present, is aware of the three basic uses for them—young leaves and stems are cooked as greens; old stems give potable, safe drinking water; and fruits are edible (Gilmore 1919, Yanovsky 1936, Morton 1968, Austin 1980, Hahn 1986, Gilliland 1975, Hogan 1978). We do not know if native people cooked leaves and stems, but they probably did. American cultures did make full use of the water in the stems. Grapevines have notable

vasculature such that no water escapes as long as cut stems are kept upright. When a stem segment about a foot long is inverted, up to a liter of water may be released.

Fruits were an important food source for native people of the South and early settlers (Medsger 1966). Swanton (1946) listed grapes as food among people from North Carolina to Texas, including the Cherokee, Creek, Chickasaw, and Caddo. Moerman (1998) added records of grapes being used as food among the Apache, Cahuilla, Cheyenne, Comanche, Crow, Dakota, Iroquois, Karok, Keres, Kiowa, Lakota, Mahuna, Meskwaki, Menomini, Ojibwa, Omaha, Pawnee, Ponca, Seminoles, Sioux, and Winnebago. It would be astounding if there was a group within the range of the genus who did not eat the fruits. Not only were fruits eaten fresh, but they were dried and stored for winter (Swanton 1946). George Catlin ([1844] 1973) was so taken with the process that he devoted a painting to grape gathering by the Caddo, a people who lived in Louisiana, Arkansas, and Texas.

The Lincecum manuscript also contained what appears to be a unique storage method used by the Choctaw (Campbell 1959). According to Lincecum's notes, the Choctaw gathered grapes near the end of the summer and put some of them in cane baskets that were then submerged in water. He says, "Grapes preserved in this way kept well through most of the winter." Campbell (1959) wrote at the time that this was the only record of storage in this way in the southeast. No other records of this practice have been found since his paper.

Europeans used the fruits for juice, syrup, jelly, jams, and wines, and they brought their Old World uses into the New. In their homeland, they also used fresh leaves as an astringent styptic. They made a medicine to combat edema, hemorrhoids, and easily broken capillary veins, and used the leaves in teas and in cooking—as stuffed grape leaf rolls. Juice from the clipped tendrils was used externally to treat rashes, and internally for intestinal bleeding, dysentery, and rheumatism. Unripe fruit juice (Syrup of Verjus) was used against obesity, and as an acidulant and a diuretic. Juice of stems was used to treat eyes. Raisins still are used as a laxative, diuretic, nutrient for hair, stomachic, for hoarseness, and in baked goods.

Southeastern people had no fermented drinks before the arrival of the Europeans, so they did not include that Old World use. Swanton (1928a) found Creeks and Sturtevant (1955) found Seminoles using grapevines for "Snake Disease" (itching spots like poison ivy, dreams of snakes), snakebites and in birth, death, and busk ceremonies (see *Pterocaulon*). Swanton (1928a) also found the Creeks using a decoction of tendrils and soft succulent ends of vines with ginseng for tonsillitis. The Choctaws used *V. aestivalis* to treat coughs (Campbell 1951). Bennett (1997) found Seminoles continuing some of those practices. Seminole Alice Snow uses *vtelokuce* (mixed medicine treatment), which includes *balbe*, with several other plants (Snow and Stans 2001). *Vtelokuce* is a treatment for a person who is weak and wants to sleep all the time. Snow instructs them to bathe in the decoction and drink some to be cured. According to Snow, *balbe* is used for many medicines, "whatever the doctor requires" including "death medicine" (Snow and Stans 2001).

Howard (1984) found the Oklahoma Seminoles using grape leaves and stems to make tea to treat diabetes. That tea is mixed with *Salix humilis* to make it more effective. Tendrils are chewed by children to prevent cavities, and used in sympathetic magic to "hold onto" a wife or husband. A cloth soaked in the tea is used to promote hair growth.

There is an ample literature on heart protection, cataract prevention, cancer protection, and slowing of aging through free radical scavenging by compounds in grapes and wines, particularly cyanidins (Maffei Facino et al. 1994, 1996, Costantini et al. 1999, Facino et al. 1999, Castillo et al. 2000, Kiesewetter et al. 2000, Wang et al. 2000, Carini et al. 2001, Ray et al. 2001, Sato et al. 2001, Singletary and Meline 2001, Bagchi et al. 2002, Cui et al. 2002, Fitzpatrick et al. 2002, Pataki et al. 2002, Preuss et al. 2002, Simonetti et al. 2002, Yamakoshi et al. 2002). Resveratrol and other stilbines have been shown to inhibit cancer, provide liver and kidney protection, act as an anti-inflammatory, and function as a natural profungicide (Oshima et al. 1995, Li et al. 1998, Bavaresco et al. 1999, Huang and Lin 1999, Paul et al. 1999, Huang et al. 2001, Soleas et al. 2001, Waffo-Teguo et al. 2001, Bertelli et al. 2002, Burns et al. 2002, Decendit et al. 2002, Gao et al. 2002, Juan et al. 2002, Schouten et al. 2002, Yoon et al. 2002).

As with everything, there are potential problems with using *Vitis* for food or medicine. Some people have developed allergies, even some that are life-threatening (Vaswani et al. 1999, Rodriguez et al. 2001, Senna et al. 2001). A few individuals have allergenic reactions resembling those from poison ivy, and even pollen can cause them (Feo Brito et al. 1999). Still, grapes continue teaching those who are willing to learn. Each fall they showed me when hunting season opened on doves in southern Florida. During that week, the mourning doves (*Zenaida macroura*) flocked to the ecological preserve on the Boca Raton campus to feed on grapes. They were joined by mockingbirds (*Mimus polyglottos*), cardinals (*Cardinalis cardinalis*), opossums (*Didelphis virginiana*), raccoons (*Procyon lotor*), and gray foxes (*Urocyon cinereoargenteus*). True to its name, *Vitis* has woven its way into our food, drink, medicine, and arts. And that is none of Aesop's "sour grapes."

### *Vittaria*

(Named by James E. Smith, 1759–1828, with Latin *vittat*, a stripe or band; akin to *vieere*, to bend, twist together; Akkadian *ebetu*, *ebiu*, to be tied, gird)

***Vittaria lineata*** (marked with lines, meaning the marginal sori)  
grass-fern (Bahamas)

*ishta taapente* (person fern, Mikasuki); *este hvlwat cokhesse* (*este*, person, *hvlwv*, high, *-at*, the one that is, *cokhesse*, beard, Creek); *yaat-chayhe echooshke* [*yá:tcáyhicô:skí*, *yaatcayhicooski*, *yaatchayhen echoonshke*] (tall person's whiskers, Mikasuki); *isti shopka chukisget* (*este*, person, *shopka*, giant, *chukisget*, beard, Creek); *istimá: ha cokhissi* (*este*, person, *mahe*, tall, *cokhesse*, beard, Creek)

shoe-string fern (Florida, Bahamas)

Sturtevant (1955) found the Seminoles using shoestring fern to treat chronic sickness and insanity, and at birth ceremonies. Bennett (1997) learned that the plant is boiled and drunk or administered in a steambath to treat depression. Resurrection fern is usually added to the mixture, and it is also used to treat senility. Snow and Stans (2001) list the plant but give no remedy using it, so perhaps Snow, like Bennett's (1997) informants, uses it in a medicine they do not wish to divulge. The Seminoles also use the leaves to

avert maladies caused by lightning striking near a person (Bennett 1997). The Guaymi of Panama use shoestring fern to treat headaches (Gupta 1995b).

***Vittaria lineata*.** a. Habit, b. Section through lower surface of fertile frond showing linear sori. c. Cross section of fertile frond, d. Sporangium. *Drawn by Priscilia Fawcett.* From Correll and Correll 1982.

### ***Voyria***

(From a name used in French Guiana)

***Voyria parasitica*** (parasitic, a misnomer; it is actually saprophitic)  
(=*Leiphiamos parasitica*, *Leiphiamos aphylla*)

*geniciana de la tierra* (wild gentian, Cuba)  
[parasitic] ghost-plant (Florida)

*Leiphiamos* (from Greek *leiphaimeo*, *leiphaimos*, lacking blood, pallid, alluding to the absence of chlorophyll) was created by D.F.L.von Schelchtendal (1794–1866) and L.K.A.von Chamisso (1781–1838), and that generic name was used until recently. Paul Maas determined recently that it should be a synonym of *Voyria* Aublet (e.g., Maas and Westra 1998). With either definition, it is a genus of 20 species growing in tropical America and West Africa (Mabberley 1997). It is one of the few mycotrophic members of the Gentianaceae.

The genus is used as a tonic, febrifuge, vermifuge, and against dyspepsia (Roig 1945).

# X

## *Xanthorhiza*

(From Greek *xanthos*, yellow, and *rhiza*, root)

*Xanthorhiza simplissima*. From Britton and Brown 1897.

*Xanthorhiza simplissima* (most-simple, unbranched) shrub yellow-root

[yellowroot]      *wi·ti·*      *nuse'?*      (*wi·ti*,      root,  
*nuse'?*, yellow, Catawba)

*Xanthorhiza* is a deciduous shrub with pinnate leaves, brownish-purple fruits, and bitter yellow roots. The genus and species were described by the Pennsylvania botanist Humphry Marshall (1722–1801) in his *Arbustum Americanum* published in 1785. The species is endangered in Florida, having been found in only four counties in the Panhandle (Coile 2000). The shrubs are also rare in southeastern Texas, although they range from there to New York (Correll and Johnston 1970). This is the only species in a genus that is endemic to eastern North America (Mabberley 1997).

The Cherokee used the crushed plant to make a yellow dye (Hamel and Chiltoskey 1975).

The Catawba used the roots for colds, ulcerated stomach, and jaundice (Speck 1934, Moerman 1998). The Cherokee made a decoction of the root for cramps, to use as a blood tonic, to treat cancer, piles, sore eyes, sore mouth, and sore throat (Hamel and Chiltoskey 1975).

### ***Ximenia*: Hog-Plum**

(Genus dedicated to the Spanish monk Francisco Ximénez, a native of Luna in the Kingdom of Aragon)

Hog-plum (*Ximenia americana*) can be identified without being seen. The flowers have a lilac-like fragrance. Even if you do not smell, you “hear” them because of all the visiting bees, flies, and wasps. If the shrubs are not in flower, people usually discover them by feel—when they run into the thorns.

Hog-plums are pantropical trees or shrubs that belong to a family of root parasites, the Olacaceae (DeFilipps 1969a, b). In 1703, Charles Plumier dedicated the genus to a Spanish monk. Ximénez came to New Spain in 1605, and joined the *Convento de Santo Domingo de Mexico*. In 1615, he published the book *Quatro libros de la natureleza y virtudes de las plantas, animales que están receuidos en eluso de medicina de la Nueva España* (Four Books on the Nature and Virtues of Plants and Animals that are Known to be Used in the Medicine of New Spain). Ximénez said his book was a translation of Francisco Hernández’s Latin publication, but it contains much original information (Standley 1920–1926). When Linnaeus studied the plants at *Hortus Cliffortianus* in 1738, he decided that Plumier’s dedication was appropriate. He continued using *Ximenia* in *Species Plantarum* in 1753.

Other people who know these root parasites also note their armament. In Brazil, people call them *ambuy* (from *abo* ‘á, with sharp hairs, Tupí). Elsewhere in northern South America, they are *espino [de] brujo* (wizard’s spine, Colombia), *tigrito [ligrito]* (little tiger, Venezuela), or spiny mountain. To some, they are just a *croc* (hook, fang, Dominican Republic, Haiti), or they resemble a *macaby [macabi]* (a spiny fish, Taino, Haiti).

In many places, the shrubs are *pepenance [tepenance]* (Guatemala, El Salvador, Costa Rica, Brazil). That name is probably from *pepe* (from *pepenar*, to sieze), and *nance* (from *mantli*, wood, Náhuatl, now the fruit of *Malphigia* or *Byrsonima*). *Pepenance* is related to *nanchicacao* (chocolate wood, Mexico, Argentina). *Nanche[i]* is a variant of *nance*, plus *cacao* (*kaj*, bitter, *kab*, juice, Maya) for chocolate. Both names are probably an allusion to using *Ximenia* as “nurse trees” in chocolate plantations.

More names allude to the fruits than other features. The most frequent comparison is to the plum (*Prunus*×*domestica*) or apricot (*P. armeniaca*). *Ximenia* is the American plum, blue sour plum, hogplum (Florida, Belize), monkey plum, mountain plum (Puerto Rico), seaside plum (Bahamas), Spanish plum (Bahamas), tallow-plum (Florida), wild plum (Belize), or yellow plum. In the French Antilles they are *prune bord de mer* (coastal prune), *prune épice* or *prune epineau* (spiny prune). Brazilians think they are more

*Ximenia americana*. Drawn by  
P.N.Honychurch.

like the apricot and say *ameixa* or *ameixero* [*ameizero*] (from *a*=the+Latin *damascena*, Portuguese). More often they note its differences compared to *ameixeira do Brasil* (Brazilian apricot) or *ameixa de espinho* [*ameixeira de espinos*, *espinha de meicha*, *espinheiro da ameixa*] (spiny apricot). People in Argentina agree with *albaricoque* (apricot). Variations in Argentina include *albarillo de campo* [*alvarillo del campo*, *albarillo del campo*] (wild apricot), *albaricoquillo* (little apricot), *albarillo* (little apricot), *albericoquillo* (little apricot), and *albericoquillo del campo* (little wild apricot).

There are several other fruit comparisons. Some think *Ximenia* fruits are like cherries (*P. cerasus*). These people say *cerise de mer* (ocean cherry, Haiti), *ciruela cimarrón* (wild cherry, Cuba), *ciruelillo* (little cherry, Mexico, Cuba, Dominican Republic, Puerto Rico), and *ciruelo* (cherry, Colombia). To many, they are more like lemons or limes because of their sour taste. Names including this view are *citron de mer* (seaside lemon, Haiti), *limoncillo [de playa]* ([beach] little lemon, Dominican Republic, Puerto Rico, Colombia), *muri lime* (Guyana), *or anger de montagne* [*oranger des falaises*] (wild [false] orange, Guadeloupe), and wild lime (USA, Belize, Guyana).

Many compare the fruits with apples. Those names include *manzana* [*manzana del diable*, *manzana del diablo*, *manzana guayaba*, *manzana guayabo*] ([devil's, guava] apple, Venezuela), *manzanilla* (little apple, Puerto Rico, Guatemala, El Salvador, Honduras, Panama), and *pommieri de Cithère* (fiddle apple). Cubans mix Spanish and indigenous words with *jía manzanilla* (little apple like *achiote* or *Bixa*, probably Taino). Another comparison with an Old World fruit resembling an apple is *membrillo de monte* (wild quince, *Cydonia oblonga*, Guatemala).

Several comparisons are unique, as in *caimito de monte* (wild *caimito*, Taino for *Chrysophyllum*, Colombia), wild olive (USA, West Indies), and iguanaberry (Jamaica). *Hevmassoli* [*heymascoli*] (Guyana) and *poonish* (Mexico) have not been translated.

The Seminoles did not know the plants until they migrated south down the Florida peninsula. By that time, they had learned the virtues of the introduced Old World peach (*P. persica*). So, the Seminoles began calling the new wild fruit they found *i:cintahã:ní* (deer's peach, Mikasuki), and the cognate with the same meaning, *co impaká:na* (*eco*, deer, *em*, its, *pvkanv*, peach, Creek). From at least the 1700s, the Seminoles ate the fruits (Bartram 1943) and used the plant against "Cow Creek Sickness" (Sturtevant 1955).

Fruits are edible raw or cooked (Ledin 1951). The kernel can be roasted and eaten but should not be consumed in quantity as it is purgative (Standley 1920–1926, Roig 1945, Morton 1968). Some consider the seeds "rather dangerous," apparently because of their laxative nature (Duke 1972), or because they contain cyanide (Liogier 1974). Fruits are used against gastric upsets (Roig 1945) and made into beer in South America (Duke 1972). European-Panamanians make "sloe gin" from the fruits (Duke 1972).

Those laxative properties gave rise to the name purge-nut (Florida). Related names are tallow-nut, tallow-wood, and tallow-plum (Florida to Panama), because of the waxy texture of the flesh on the drupe. The laxative properties are included in the names *cagalera* [*cagalero*, *cagadera*] (diarrhea, Honduras, Belize) and *fransman moppe* [*fransmanmope*] (Frenchman's complaint, Sranan, Suriname). Probably, they are implied in *tocote de monte* (wild *tocote*, often a name for *Jatropha*, Guatemala). The name *unsicacá* [*uncincaca*] [*de montaña*] is said to be from the Zoque language of the Isthmus of Tehuantepec in Chiapas. Perhaps the Zoque word *caca* is related to Mayan *kajkab* (bitter). Still, the name looks suspiciously like Spanish *un sin caca* (one without feces), maybe from an advanced stage of purging by *Ximenia*.

The Arawak name *wiri* (herb, Arawak, Guyana, Suriname) could refer to the medicinal fruits or to the edible leaves cooked as a potherb (Morton 1968, Duke 1972, Freiburger et al. 1998). The concept of purging may also be related to the name *k'uk-ché* [*kic-che*, *k'uk-che*, *xkukche*, *xkuk-ché*, *xk'uk-ché*] (*k'uk*, renews, *ché*, tree, Maya, Yucatan, Belize). Purging and emesis are part of cleansing rituals throughout the world.

Wood of *Ximenia* is yellow-red, hard, heavy, and fragrant (Little et al. 1974). The odor prompted people to call it sandalwood (USA, West Indies) and false sandalwood (USA, West Indies). However, not everyone is that complimentary. To some, it is the *bois puant* (stinking tree, Windward Islands). Others think it is as hard as *ishiri* (*isri*, iron, Dutch Antilles). A compliment is to say it is *yaná* (originally buttonwood, *Conocarpus erecta*, Taino, Cuba), yellow sanders (USA, West Indies), or just *pata* [*pata de monte*] (mountain wood [literally foot, but colloquially for wood], Argentina). The allusion in *chocomico* (*choco mico*, black monkey, Honduras, Nicaragua) is not clear.

To people who appreciate the plant, it is *teukra* [*teu-kra*] (variant of *teocali*, from *teotl*, god, *calli*, house, Náhuatl, Costa Rica). However, *saaxnik* (*sak*, white, *nik*, small flower, Maya, Yucatan) is almost Japanese *haiku* poetry.

In addition to being a laxative, a syrup made from the fruit is used in the West Indies and Panama for dropsy, rheumatism, and other problems (Standley 1920–1926, Roig 1945, Duke 1972). Baths of the astringent bark have been used in Brazil against excessive menstruation (Roig 1945), and in many tropical countries to cure skin diseases (Liogier 1974). In Panama, the roots are chewed to stop toothache, against sleeping sickness, fevers, ringworm, venereal disease, and to stop vomiting and diarrhea (Duke 1972). Oil extracted from the seeds (Standley 1920–1926) is used for cooking, soap, and lubrication (Morton 1968b, Eromosele et al. 1994, Eromosele and Eromosele 2002).

Among the oils, the plants contain mandelonitrile lyase (Kuroki and Conn 1989), oleanene palmitate (Fatope et al. 2000b), and acetylenic fatty acids (Fatope et al. 2000a). Some of those compounds have potential as pesticides (Fatope et al. 2000a). Laboratory studies show that extracts from *Ximenia* also are antiviral (Asres et al. 2001), antibacterial (Fabry et al. 1996b, 1998), fungicidal (Fabry et al. 1996a), antimalarial (Benoit et al. 1996), insecticidal (Fatope 2000a), and molluscicidal (Kela et al. 1989), and may be useful in the treatment of sexually transmitted diseases (Ndubani and Hoger 1999).

After encountering them for weeks, some of my graduate students decided that hog-plum was incorrectly named. One of our tasks, while working for Palm Beach County, was to locate gopher tortoise (*Gopherus polyphemus*) dens. We usually found burrows when thorns on hog-plum growing beside them tore our skin and clothing. So, the students renamed the plants the “Tree from Hell.” From hell maybe, but the fragrance of the flowers is heavenly.

*Xyris*

(Greek name for some plant with two-edged leaves, from *xyron*, a razor, reapplied by Linnaeus; some say *xyris* was applied by Pliny, A.D. 23–79, to a wild iris)

*Degenbinse* (sword rush, German)  
yellow-eyed grass

*Xyris ambigua* (doubtful, alluding to the difficulty in distinguishing this species from others)

*ʔakó:cfáni:kî*                      *ʔa,*  
 arrow,                      *ó:cfáni,*                      *[rakó:cfáni: kî]* (                      Mikasuki);

*ʔi:opaykocín* *ʔe*,  
 [ri:opaykocín] ( *opiyetv*, twisted, *oce*, small, Creek)  
 coastal-plain yellow-eyed grass [coastalplain yelloweyed grass, yellow  
 eyed-grass]  
 vare goldies

*Xyris baldwiniana* (named for its discoverer, William Baldwin, 1779–1818, a physician in Pennsylvania)

Baldwin's yellow-eyed grass [Baldwin's yelloweyed grass] (a book name)

***Xyris brevifolia*** (short-leaved)  
short-leaf yellow-eyed grass [shortleaf yelloweyed grass]

*Xyris caroliniana* (of Carolina)

*Xyris chapmanii* (named for Alvin Wentworth Chapman, 1809–1899, who wrote the first flora of the southeastern United States)

*Xyris difformis*. Drawn by  
P.N.Honychurch.

Carolina yellow-eyed grass [Carolina yelloweyed grass]

*Xyris difformis* (of two forms) bog yellow-eyed grass [yelloweyed]

*Xyris elliottii* (for Stephen Elliott, 1771–1830, author of *A Sketch of the Botany of South Carolina and Georgia*, published between 1821 and 1824)

Elliott's yellow-eyed grass [yelloweyed] (a book name)

Jan Gronovius created the genus *Xyris* from an old Greek name of doubtful application in his *Flora Virginica*. He used the phrase-name *Xyris foliis gladiatis* (xyris with leaves like swords). At first, Linnaeus followed Gronovius in using the phrase name in the *Flora Zeylanica* of 1747 but then decided to call the plants *Xyris indica* in 1753. Linnaeus seemed not to be bothered with plants occurring on the opposite sides of the world, and

wrote, "*Habitat in Indiis*" (Grows in the East and West Indies). In 1819, J.E. Smith recognized that the Linnaean concept was a mixture of New and Old World taxa. He restricted the Linnaean name to the Old World herb, describing *X. torta* for the American plant (Kral 1966, Steve Cafferty, personal communication 2003).

Thomas Walter described *X. caroliniana* (from South Carolinas) in 1788. André Michaux knew a single species (*X. jupicai*) in Florida, which he described (Taylor and Norman 2002); he also gave us *X. brevifolia* (from Georgia) in 1803. The other species in Florida were discovered as late as 1990 (cf. Kral 1983c, Bridges and Orzell 1990).

Since 1753, *Xyris* has grown to a genus of 200 to 400 species known in the tropics and warm regions of the world (20 Australia, 25 Africa) (Mabberley 1997). Kartesz (1994) listed 24 species for North America. It is understandable why early explorers did not take much notice of *Xyris*; they are grasslike plants intermixed with real grasses and sedges. Their flowers, with three yellow petals, all look similar, and it is only with more sophisticated magnification that people were able to examine the fine details that are used in distinguishing many species. Indigenous people, without magnifying lenses, perhaps recognized fewer species than Europeans.

All uses found among indigenous people were in the southeastern United States. Since the genus does not occur in the Great Plains (Barkley 1986) and is known from only two counties in Missouri (Steyermark 1963), it is not too surprising that Missouri River people did not utilize them (Gilmore 1919).

The Cherokee are the people farthest north known to use the plants. They made an infusion of *X. caroliniana* roots to treat diarrhea (Hamel and Chiltoskey 1975). While it is not clear, they may also have taught settlers other uses. According to Uphof (1968) and Lewis and Elvin-Lewis (1977) the same species has been used in home remedies for skin problems as well as colds and pulmonary ailments.

*Xyris caroliniana* was not the only species used for lung and chest problems. The Seminoles used "an infusion of [*X. ambigua*], and doubtless other, species of *Xyris*...in cases of colds and pulmonary disorders" (Small 1933). *Xyris elliotii* was used identically, and an infusion of the herbage was rubbed on the chest to treat colds (von Reis and Lipp 1982).

Little is known about the chemistry of *Xyris*. Tannins, saponins, calcium oxalate crystals, isocoumarins, anthraquinones, and sometimes aluminum have been found in several species (Fournier et al. 1975, Cronquist 1981, Ruangrunsi et al. 1995). All of those are notoriously bioactive chemicals and may account for some of the medical applications.

Historically, there were magical applications of *Xyris* among the Seminoles. Josie Billie, one of Sturtevant's (1955) informants, recounted an ancient use for *X. ambigua*. According to him, the *Xyris* flowering stem is twisted, as one of the supernatural thunders is also twisted. Therefore, the effectiveness of the magic depends on the thunders. To invoke this magic, the sorcerer fasts for 2 or 3 nights and 4 whole days, breaks off four *Xyris* flowering stems, and sends them "like arrows," with the flower at the butt end, for great distances ("thousand miles"). No one in the 1950s could do this any longer.

# Y

## ***Yucca*: From Silk-Grass to Spanish Dagger**

(From Taino *yuca*, originally the root of *Manihot esculenta*, while the plant was called *yucubia*; reapplied to this monocot because of confusion probably dating from Bauhin's *Pinax* of 1623)

***Yucca*.** *Yucca aloifolia* (left). Drawn by P.N.Honychurch. *Yucca filamentosa* (right), with fibers on leaf margins. From Britton and Brown 1896.

With classes on the beaches, I always tried to find a Spanish dagger (*Yucca aloifolia*). I would cut off a leaf while I explained how the plant was important to indigenous people. As we continued, I stripped the flesh from the fibers, always leaving the apical spine intact. When finished, I showed them the “needle and thread” and told them how its names changed from silk-grass to Spanish dagger.

When the Europeans arrived in the Caribbean, they found the Taino people using roots they called *yuca*. Somehow, the newcomers began calling two totally different kinds of plants by the single name.

The important food plant was *Manihot esculenta* (Hedrick 1919, Sauer 1969). Martyr (1555) wrote, “*iucca* is a roote, whereof the best and most delicate bread is made, both in the firme land [mainland] of these regions and also in ilandes.” Gaspar Bauhin knew the same plant in 1623, when he called it *Manihot inodorum sen yucca foliis cannabinis* (odorless manihot or yucca with leaves like Cannabis). In the same book, Bauhin listed a second species (*Y. aloifolia*) that he called *Yucca foliis aloes* (yucca with leaves like aloe).

In Spanish, the original *yuca* of the Tainos was retained for *Manihot*. The *Agave* relative *Yucca* is usually *palmito* [*palmito*] (little palm), or simply *palma* (palm), although most Caribbean people understand *yuca* for that plant too. Indeed, *yuca* [*yucca*]

(Dominican Republic, Guadeloupe, Martinique) is a common name for both in several areas.

Why this confusion took place is not clear. All the original references were to *Manihot*. Of *Yucca*, Santamaria (1959) says, "*La raíz ni es comestible, ni es verdad que de ella se extraiga harina*" (The root is not edible, nor is it true that one may extract flour from it). In spite of this, Liogier (1974) says of *Y. aloifolia*, "*La raíz carnosa contiene almidón y es comestible al igual que la Yuca*" (The fleshy root contains starch, and is edible just like *Manihot*). The common name Indian bread plant (Hispaniola) makes me wonder if we have missed something.

A trait arguing against eating the starch from the roots of *Yucca* is their saponin content (Oser 1966, Dewidar and el-Munajjed 1970, Stohs et al. 1974, Sener and Turkoz 1987, Tanaka et al. 1996, Sen et al. 1998, Miyakoshi et al. 2000, Uematsu et al. 2000, Oleszek et al. 2001, Plock et al. 2001). Indeed, in Mexico, a generic term for the genus is *amole* (soap, Náhuatl), and the Mexicans use extracts from the roots for washing. Howard (1907) even recorded a Seminole woman at Lake Okeechobee in 1856 "digging some roots that had a saponaceous juice she powdered them and soaked them in water, washing her hair with the lathery substance till it was smooth and glossy." The lake is not a usual area for *Yucca* but, if Howard identified it correctly, the shrub would have been cultivated.

Regardless of its origins, by the 1600s *Manihot* and *Yucca* were confused. It took Linnaeus to straighten them out, and in 1753, he recognized four American species of *Yucca*—*Y. aloifolia*, *Y. gloriosa*, *Y. draconis*, and *Y. filamentosa*. *Yucca draconis* is now a variety of *Y. aloifolia*.

The oldest reference we have for *Y. aloifolia* in Florida was from H. d'Escalante Fontaneda in 1575 (Austin 1980). That former captive of the Calusa wrote of women's clothes on Matacumbe Key that they were "*vnas yerbas que nazen de unos arboles estos yerbas paresen lana aunque son diferentes*" (some grasses that grows on trees, the herbs looks like wool although they are different). Of the women at Abalachí, he wrote that they covered themselves with "*vnas pajuelas que nazen de los arboles a manera de estope o lana y no es*

*blanco sino pardo i con aquellas yerbas se cubren dellasa la redonda a la sinta*" (some straw that grows on trees like burlap or wool and it is not

white but brown and with these herbs they cover themselves about the waist). The fibers were from *Y. aloifolia*, and not *Tillandsia usneoides* as Smith (1854) and Small (1933) contended. Farther north, Harriot

([1590] 1972) and Sir Thomas Gates, governor of Virginia in 1610, recorded indigenous skirts of *Y. filamentosa* much like those used in Florida (Coffey 1993). Indeed, Strachey ([1612] 1953) made numerous comments about "silk grass" use by the Virginian Algonquian tribes.

Dickinson (1699) first noted that the Hobé men near Jupiter Inlet wore loin cloths of palm with a "horsetail of a bunch of silk-grass exactly resembling it, of a flaxen color." Bernard Romans ([1775] 1961) also called *Y. aloifolia* silk grass. Typically, William DeBrahm ([1772] 1974) could not make up his mind and said they were *iuca*, and *palmeta royal*. From the same period, Bartram ([1791] 1958) agreed with palmetto royal.

Small (1933) recorded that leaves of all south-eastern species were used by pioneers to make ropes and string for hanging up cured meats. In the early 1970s, I found fishermen on Great Inagua near the Bahamas still using the cord made from *Yucca* to hang their bonefish (*Albula vulpes*) to dry. Fiber from the leaves is recorded in *maguey silvestre* (wild *maguey*, Taino, Cuba). People also say *penguin* [pingouin] (Haiti), probably because the sharp leaves remind them of *Bromelia pinguin*, another fiber plant.

It was late when *Yucca* became Spanish-bayonet [bayonette] (by 1843, Florida, Dominican Republic) and Spanish-dagger (Florida), but those names reflect the Mexican name *izote* [icizotli] (from *ixtli*, *xotla*, and *ixotla*, stab someone in the face, Náhuatl). Related names are still used, as *bayoneta* (Cuba, Dominican Republic, Puerto Rico), *bayonette* (Haiti), *espino* (spine, Cuba, Dominican Republic), and sword plant (Bahamas). *Piñon de puñal* (dagger pine, Cuba) contains similar intent.

Aloe yucca (USA, Puerto Rico) harks back to the 1600s. Plukenet made the comparison in 1696 as *Aloe, yuccae foliis* (Aloe with leaves like yuca), as did Kaspar Commelin in 1703 with *Aloe americana, yuccae folio* (American aloe with leaves like yucca).

## neme'?

*Yucca* to the Catawba was *sara'k* [surá-k] (bear grass). The Choctaw said *nita inpisa* [neta pisa] (*nita*, bear, *in*, its, *pisa*, eyes). Choctaw relatives the Creeks say *sowenv* [suwénv, sowi:nâ], and to the other Seminoles the plant was *pasalátki* (Mikasuki). The Koasati also say *passá*. Apparently, all are simple untranslatable names, although the Mikasuki and Koasati include *pasa* (*Eryngium yuccifolium*). The Alabama said *tosiina istataakka* (*tosiina*, from Spanish *tocino* for bacon, *ist-*, it is, *atákkaaka*, hanging). The name is derived from their use of the sharp point on the leaf and its fibers to hang meat for smoking (Sylestine et al. 1993).

There is no obvious reason why these spiny shrubs are *salesepareille* (sarsparilla, usually used for *Smilax*, Guadeloupe, Martinique). Similarly, it is not clear why the plants are called *flor de Jericó* (flower from Jerico, a city in Palestine, Dominican Republic) or just *Jericó* (Dominican Republic). Perhaps the reference is related to the old name “Lord’s candlestick” (USA) for several *Yucca*.

One species called Our Lord’s candles is *Y. filamentosa*, which grows from Maryland west to Tennessee and Kentucky, and south to Georgia, Florida, and Louisiana. That plant too was called silk-grass, and had the same uses as *Y. aloifolia* (Coffey 1993). Whitford (1941) recorded a cord made of *Y. filamentosa* among pre-Columbian archaeological remains from Ohio. Yanovsky (1936) said the fruits were eaten in the southeastern states.

Other names for *Y. filamentosa* are Adam’s needle, bear-grass, bear’s thread, Christmas bells, Confederate flax, curly hair [yucca], Eve’s darning needle, Eve’s thread, grass-cactus, needle palm, soaproot, soapweed, Spanish dagger, spoon-leaf yucca, and thread-and-needle. The Catawba, Cherokee, and Nanticoke used root extracts to treat skin diseases, rheumatism, and gonorrhea through the 1600s and 1700s (Speck 1937, Taylor 1940, Coffey 1993, Moerman 1998). They considered it sedative, among other properties. The Cherokee also used the roots to kill fish and wash blankets (Hamel and Chiltoskey 1975, Moerman 1998).

Much less common is *Y. gloriosa* (Brunswick, Dare, and Onslow Counties, North Carolina, Charleston, South Carolina, Georgia, and Leon and Franklin Counties, Florida), an endangered plant in Florida (Coile 2000). This species is famous for its names Lord's candlestick and Roman-candle (USA). It is also known as Spanish bayonet and palm lily, but it is usually called mound-lily yucca. The comparison of growth to a mound is reflected also in *sak tuk* (white mound, Maya, Yucatan) for *Y. aloifolia*.

Plants still are eaten in many places. People in most of the Caribbean region eat flowers in salads, and often cook them with eggs (Standley 1920–1926, Leon and Alain 1946–1954). Morton (1968b) contended that the buds are edible raw, but taste better when boiled or roasted as a vegetable. Taste varies, apparently from plant to plant and with the age of individual flowers. Students were often amused when I tasted flowers to show them they were edible and frowned at the bitter taste. Morton (1968) also considered the raw fruits edible, but most find them rubbery and bitter. Flower stalks are also peeled, boiled, and eaten.

According to Bushnell (1909), the Choctaw boiled the mashed root with grease or tallow and used the healing salve for various problems. Taylor (1940) also found the Koasati using *Yucca* medicinally. However, by the time Sturtevant (1955) worked with the Seminoles, they no longer used the plants. In Hispaniola, tea is made of the young leaves as a diuretic (Liogier 1974). *Yucca* has been used in many remedies probably because it contains saponins, glycosides, and steroids (Blunden et al. 1965, Lazur'evskii et al. 1975, Stohs et al. 1975, Nakano et al. 1991a,b, Kishor et al. 1992). Laboratory studies indicate that compounds from *Yucca* are antitumor (Ali et al. 1978), antiviral (Hayashi et al. 1992), antioxidant (VanderJagt et al. 2002), have antiplatelet effects

(Olas et al. 2002), and are useful against giardiasis and *Leishmania*

(McAllister et al. 2001, Plock et al. 2001). The resveratrol and other stilbines have been shown to inhibit cancer and give liver and

kidney protection. They are anti-inflammatory and function as a natural antifungicide (Oleszek et al. 2001, Ueno et al. 1997). However, there are potential problems with allergenic reactions (Kanerva et al. 2001, Munno et al. 2001).

The most visible use in the past few decades for all *Yucca* in the Caribbean has been as living fences or as ornamentals in yards (Leon and Alain 1946–1954, Liogier 1974). Especially in rural areas, but also in places like Fort Lauderdale and Miami, *Yucca* is planted near houses and adorned with eggshells on the tips of the leaves. Some enterprising moderns substitute segments of egg cartons for the shells. Either way the daggers become more visible.

# Z

## *Zamia*: Coontie

(From *azaniea nueces*, dried-up nuts or Latin *zamia* or *samia*, to hurt or damage)

*Zamia integrifolia*. a. Male plant, b. Tip of leaf segment (left), leaf (above), leaf segments attached to rachis (right), and base of lower leaf segments showing reflexed margins, c. Cataphyll. d. Microspore cone. e. Microsporophyll (below) and microspore sac (above), f. Megaspore cone (right) and megasporophyll (left), g. Seed cone. h. Megasporophyll with

seeds. *Drawn by Priscilla Fawcett.*  
From Correll and Correll 1982.

Before going to Florida, I had seen cycads (from *kykas*, a palm, Greek) growing in greenhouses at the Missouri Botanical Garden where I did my graduate work. These ancient conifer relatives have been called living fossils, and they were widespread and pervasive throughout the Mesozoic, 250–265 million years ago (Schneider et al. 2002). Partly because of that, I was anxious to see them in the wilds of southern Florida. In the Everglades National Park, I found coontie (*Zamia integrifolia*) in the pinelands. They were not very impressive, but they did look a little like palms.

I wondered why Linnaeus called them *Zamia*, and found that he followed Pliny the elder (A.D. 23–79). Pliny had called a pinecone *zamia* and for pine nuts wrote *azaniea nueces* (dried up nuts). In Linnaeus's usual delight for multiple meanings, the genus could either mean their cones looked dried up (they do), or come from Latin *zamia* or *samia* (to hurt or damage). As Linnaeus was a physician, he surely had learned of poisons in the plants.

The poisonous compounds in *Zamia* include the glucoside cycasin (Lampe and McCann 1985, Nellis 1997), flavones such as amentoflavone, bilobetin, sequoiaflavone, and ginkgetin (Meurer-Grimes and Stevenson 1994, Hocking 1997), vicilin-like seed proteins (Braun 1996), alkanes in the foliar waxes (Osborne et al. 1993), azoglucosides, and nonprotein amino acids (Schneider et al. 2002). It is no surprise that Morton (1968b) recorded, "Water used to leach the [*Zamia*] starch was red from poisonous compounds, and would kill cattle or other animals drinking it." Even turkeys eating the seeds were poisoned (Morton 1968b) in spite of *Zamia* dispersal by birds (Eckenwalder 1980a).

In another puzzle, I found that the word coontie [contee, conte, contie, comptie, coontah, coonta] came from Florida's Seminoles. William Bartram ([1791] 1958) first wrote "coontie" in 1791. He wrote of eating with Creeks on the Suwanee River a "cooling sort of jelly, which they call conte; this is prepared from the root of the China brier (*Smilax*)" He also wrote that the reddish flour, "mixed with warm water and sweetened with honey, when cool, becomes a beautiful, delicious jelly, very nourishing and wholesome; they also mix it with fine Corn flour, which being fried in fresh bear's oil makes very good hot cakes or fritters."

To the Creek people there are two words for edible roots. One Creek word for them is *vhv* [áha], while their relatives say *a:hi* (Mikasuki) or *ahe* (Choctaw). The other Creek word is *kunte* [konte, kontí, kunti, kontik, kantik], and its Muskogean cognates are *kantiki* [contee] (Mikasuki), *kanták* (Houma), and *kantak* (Choctaw). *Aha* is generic for roots, while *kunte* historically applied to the rhizomes of *Smilax*.

After the Seminoles were driven south down the Florida peninsula, they found a new plant with edible roots (technically stems), *Z. integrifolia*. Since they now had two kinds of *kontí*, they distinguished between them. The old familiar *Smilax* became *kunte cate* [kontí chate, conti chatee, coontie chabi, coonti chacli, coonti chatee] (red coontie, Creek), which is sometimes translated as "red flour" (Speck 1941, Sturtevant 1955). *Zamia* roots were dubbed *kunte hvteke* [conti hatke] (white [bread] root, Creek). Both kinds of *kunte* became the basis of the Seminole diet in the gruel or soup they call *sofkee*.

Because *Zamia* was poisonous, it required a more elaborate preparation than *Smilax*. Accounts of how the stems were made edible vary in details (Yanovsky 1936). According

to Morton (1968b), stems were scraped or peeled, pounded, grated, ground, or boiled until soft and mashed with abundant water. The mixture was then drained and the resultant starch was allowed to dry in the sun. Bennett (1997) was told that the stems were grated (using corrugated roofing with nail holes) and collected in a vat. That material was then allowed to ferment for up to 7 days. The odor of the mixture indicated to those who knew the process when the coontie was ready. This mixture was spread on a cloth sheet, and squeezed to eliminate moisture. The squeezing process was repeated several times, and then the mixture was spread out and allowed to dry. A powdery flour is the final substance. To make *sofkee* Seminoles cooked the mash, instead of drying it, with meat and vegetables.

Coontie has an important place in Florida history although few residents in Fort Lauderdale know that the plants started their city. The Seminoles in the early 1800s sometimes called what is now Middle River the *Colohatchee* (*kala*, oak, or *colowa*, colored, *hatchee*, creek), but they also called it the “coonti grounds” (Simpson 1956). In the 1830s, Motte (1963) wrote that the river was “called by the Indians *Coonte Hatchee*, the country around it being the great coonte region, where this root abounds; which being prepared by the Indian women for their bread by a simple process of grating and washing.” The product was so important it came to be called “Seminole bread” (Nellis 1997).

Into this important Seminole region came a white man named William Coolie. He, his family (wife, three children), the children’s male tutor named Flinton, and their slaves settled beside the river in what is now downtown Fort Lauderdale. They proceeded to cut down the forest and created a coontie-processing business for their “plantation.” On 6 Jan. 1836, several Seminoles attacked and killed everyone except Coolie himself, who was away, and the slaves. Between Dec. 1835 and Jan. 1836, nearly all the plantations between Cape Florida and St. Augustine, mostly on important coontie grounds, were destroyed (Motte 1963). Two years later Major William Lauderdale and his Tennessee Volunteers built the fort that later bore his name. While Patsy West and Betty Mae Jumper (1998, 2001) argued that the Coolie incident was coincidental to the other attacks, that incident and the others precipitated the Second Seminole War.

Although not widely known, coontie was familiar to Europeans long before the Seminole war. *Zamia* was recorded in Cuba by Bartolome de Las Casas in the 1550s when he wrote “*hay en los montes otras raices, que llamaban los indios guayaros*” (there are other wild roots that are called by the Indians *guayaros*) (Coll y Toste 1972). That word remains in Spanish with *guayará* (Taino, Cuba), the name for *Z. integrifolia*. Other Cuban names for *Z. integrifolia* are *yuquilla de paredón* (little execution wall yuca) and *yuquilla de ratón* (little mouse yuca), both allusions to the poisonous nature of the plants. Apparently, the first record of *Zamia* in Florida was by Fontaneda ([1575] 1944), who wrote of *pan de rraises* (bread of roots) among the Glades people (Austin 1980).

A related species, *Z. debilis*, grows nearby. In Hispaniola it is *guáyra* [*guáyiga*], a variant of *guayará*. In Puerto Rico, it is *marunquay* (Taino), which Coll y Toste (1972) records is a “*raíz de una planta que da fécula*” (root of a plant that gives starch).

People also began calling *Zamia* starch “Florida arrowroot” to distinguish it from the other kind. Hans Sloane had used “arrowroot” in 1696 for starch from *Maranta*. He did that because originally “arrowroot” starch was medicinal—to absorb poisons from wounds, especially those from poisoned arrows. Later, it came to be used for other

medical purposes. During the Second Seminole War, army surgeon Jacob Mott (1963) wrote, “[coontie] constitutes the arrow-root of many Apothecaries throughout the United States, and which I frequently used as such with the sick in Florida.” According to Culbreth (1910), arrowroot was “used as demulcent, nutritive food for infants, convalescents, bowel or urinary troubles; in 5 p[er] c[ent] solution with water or milk by boiling and flavoring with vanilla, lemon juice, etc.; also used in puddings.” There was a factory producing arrowroot in Miami in 1911, and the flour was used to make “arrowroot biscuits” (Workman 1980). Arrowroot flour also has been used in baby food, chocolates, and spaghetti (Nellis 1997).

*Zamia integrifolia* grows in the Greater Antilles, the Bahamas, Florida, and southern coastal Georgia (Ward 1979, Eckenwalder 1980b, Correll and Correll 1982, Kral and Robinson 1983, Stevenson 1987, Jones and Coile 1988, Whitelock 2002). Its prominent synonyms are *Z. floridana* and *Z. pumila*. Oddly, the shrubs are called bay-rush (Bahamas) and bulrush [bull rush] (Cayman Islands) in the Islands. Typically, those common names are given to Cyperaceae or Typhaceae.

The same compounds that make raw coontie poisonous to humans are crucial elements in the development and maintenance of mutualism (pollination) and parasitism (herbivory) by cycad-linked insects (Schneider et al. 2002). The toxin cycasin now is implicated with retaining the relationship between the pollinator (the weevil, *Rhopalotria mollis*) and the specialist herbivore (the aposematic Atala butterfly, *Eumaeus atala*).

Coontie was almost extirpated from Florida along with its spectacularly colored butterfly herbivore by the 1950s (Klots 1951). Then, by cultivating the plant and moving the butterfly to the new populations, both seem to have stabilized (Kimball 1965, Ward 1979, Kral and Robinson 1983, Scott 1985). Organisms with such complicated and long histories, even with humans, should remain on the planet—they teach us a great deal.

### ***Zanthoxylum*: Prickly Ash, Hercules’s Club, and Wild Lime**

(From Greek *xanthos*, yellow, *xylon*, wood)

My introduction to *Zanthoxylum* was when I grabbed a tree to slow my descent down a hillside. The spines on the stems left what I thought would be permanent scars on the palm—and I fell anyhow. Later I learned that the plant was *Z. americanum*, prickly ash or *frêne épineux* (Quebec).

The tree that perforated my palm barely extends to Florida in Levy, Gadsden, and Liberty Counties. More common in the state is *Z. clava-herculis*, usually called Hercules’s club. Linnaeus gave it that Latin name in 1753, and some say the English translation only appeared in 1847. The reverse seems likely, with the common name preceding the Latin.

*Zanthoxylum clava-herculis* reaches down the peninsula to Lake Worth in Palm Beach County, and to Tampa Bay on the west coast. Historically, the species reached Miami. Both it and *Z. americanum* figured prominently in native American medicine. The Houma called the trees *frêne piquant* (pungent ash). Otherwise, we have only English names for *Z. clavaherculis*, and Linnaeus ([1753] 1957) was obviously impressed with its armament. Many Americans, also impressed, say prickly yellow-wood, tear blanket, wait-a-bit, wild orange, sea ash, and yellow pricklyash.

People who have tasted the bark call it pepper wood, rabbit gum, sting tongue, tongue-bush, and toothache [tree]. The flavor is much like the sedative the dentist swabs on your gums before giving a shot of novocaine. Maybe they are related compounds. Either way, using the plant to relieve toothache was a prominent application by native Americans and European immigrants. Millspaugh (1892) described his own experiment: "I found that, upon chewing the bark for relief of toothache, speedy mitigation of the pain followed, though the sensation of the acrid bark was nearly or fully as unpleasant as the ache, and so painful finally in itself that I abandoned its use." Formerly *Z. clava-herculis* was called "pillenterry" a corruption of "pellitory," and a misnomer by Catesby (1731–1732) and Barton (1810).

According to Moerman (1998) and others, uses of *Z. americana* and *Z. clava-herculis* cannot be separated. One or both were used by the Alabama, Algonquin, Atapaka, Biloxi, Cherokee, Choctaw, Comanche, Creeks, Delaware, Houma, Illinois-Miami, Iroquois, Koasati, Menomini, Meskwaki, Mohegan, Ojibwa, Omaha, Osage, Pawnee, Potawatomi, Seneca, and Winnebago.

To Alabama speakers *Zanthoxylum clava-herculis* was *ittohalokpa* (*itto*, tree, *halokpa*, sharp-pointed) and *natikasahlichì* [*innatikasahlichì*, *natikasaalichì*] (*nati*, tooth, *kasahlichì*, cooling). They made wedges from the hard wood and also applied the inner bark to gums to relieve toothache (Sylestine et al. 1993). The Choctaw said *nuti alikchi* (*nati*, tooth, *alikchi*, doctor) or *ikhinsh patassa* (*ikhinsh*, medicine, *patassa*, flat). The Creeks of Oklahoma call it *'tokvsyppe* [*tokvsap'pv*] (*eto*, tree, *kvsvppe*, cold), which is the same idea as *ittokasáhka* [*ittohalokpá*] (*ittó*, tree, *kasáhka*, lower fever, Koasati). The Biloxi said *anisni hudi* (*ani'*, water). The Atakapa called them *ci'wat te ne'c* (*ci'wat*, alligator, *te*, plural, *ne'c*, tree).

According to Rafinesque (1820), a common name for *Z. americanum* among the "Western tribes" was *hantola*. Hunter ([1823] 1973) confirmed that the Osage name was *han-to-la*. The Ojibwa call it *gawa'-komic*. The Pawnee simply called it *haknsits* (thorn). Omaha men used the fruits as perfume (Gilmore 1919).

Indigenous people also used these two plants to treat bronchitis, tuberculosis, for various infections (draw off pus, itch, oozing or ulcerated external conditions, quinsy, sore throat, sores, swellings, and ulcers), to treat hemorrhages and intermittent fever, for kidney problems (including gonorrhea), flatulence, dropsy, rheumatism, to purify the blood, and as a general tonic (Lawson [1714] 1937, Catesby 1731–1732, Carver 1779, Loskiel 1794, Schöpf [1798] 1903, Barton 1810, Hunter [1823] 1973, Millspaugh 1892, Michaux 1904–1907, Nuttall 1905, Lloyd 1921, Swanton 1928a, Speck 1941, Kinietz 1965, Murphee 1965). They were also used as a cathartic and an emetic (Vogel 1973).

Modern herbalists consider the bark and berries stimulants to the circulatory, digestive, and lymphatic systems. Like their native American teachers, they

***Zanthoxylum*.** *Zanthoxylum americanum* (top left). From Britton and Brown 1897. *Zanthoxylum clava-herculis* (top right). Flowering and fruiting branches. From Sargent 1905. *Zanthoxylum fagara* (lower left). Drawn by P.N.Honychurch. *Zanthoxylum flavum* (lower right). Flowering and fruiting branches. From Sargent 1905.

prescribed both for rheumatism, skin disease, nervous headache, varicose veins, congestion, and as a convalescent tonic, which may have anticancer properties (Bremness

1994, Bown 1995, Duke et al. 2002). Bark was in the U.S. Pharmacopoeia from 1820 to 1926 and in the National Formulary between 1926 and 1947. Berries were in the National Formulary from 1916 to 1947.

The tropical *Z. fagara*, which grows in the southern two thirds of the Florida peninsula, was used at least as much as the others (Standley 1920–1926). The bark is sudorific and acts as an arterial and nervous stimulant. Leaves and bark have been used as a spice because of their pungent taste, and the bark gives yellow dye (Standley, 1920–1926). Some of *Z. fagara*'s uses are reflected in its common names, such as *cha'ach* (to chew, Maya, Yucatan; incorrectly recorded as *cha kah*, which is the name for *Bur sera simaruba*), and *wi'puuy* [*huipuy*] (*puuy*, mouth, Huastec, San Luis Potosí). Surely *salitrero* (saltpeter) also is from the taste.

Many names allude to the tree's prickly nature. Some compare *Z. fagara* to spines as in *espino* (spine, Cuba), *espino amarillo* (yellow spine), and *espino rubial* [*pino rubial*] (blond spine, Puerto Rico). Others think *Z. fagara* more like claws and say *arañagato* [*aruña gato*] (cat catcher, Cuba, Venezuela), *o'ouse suctu* (lion's claws, Mayo, Sonora), and *uña de gato* [*uñagato*] (cat claw, Dominican Republic, Tamaulipas, Colombia). A few even compare *Z. fagara* to horns, with *chivo* (goat, Cuba), and *tarro de chivo* (goat horn, Cuba). To some, it is *amoroso* (lover, Isle of Pines), and others think it simply *chincho* (irritating tree, from *chinche*, Honduras). *Zanthoxylum fagara* is even considered an *alacrán* (scorpion, Chiapas).

People also compare *Z. fagara* with other prickly plants, as in *palo [de] zarza* (blackberry tree), *zarza de tomeguín* (hummingbird's blackberry, Cuba), or simply shorten the latter to *tomeguín* (a hummingbird, Cuba). The name *garabatlillo* (little hook, Mexico) alludes to the similarly prickly *Mimosa*. To others, it is *pinzanillo* (little pincers, related to *pinzan*, a common name for *Pithecellobium dulce*). Another comparison with *Pithecellobium* is *tenaza* (tenacious), a name used in the northern part of Mexico. The name *ceibilla malacapa* (*ceibilla*, little ceiba, Taino, and *malacapa* from *malacatl*, spindle, Náhuatl, but the name of spiny legume *Myroxylon horridum*) is a double allusion to the spiny trunks.

It is common to compare *Z. fagara* with its *Citrus* relatives. Some of those names are lime prickly-ash (USA), prickly lime (USA), *limoncillo* (little lemon, Sonora, Sinaloa, Cuba), *mata-la-sed* (thirst killer, Sonora), *naranjillo* (little orange, San Luis Potosí), and wild lime [tree] (Florida).

A widespread name in the Río Grande valley of northern Mexico and adjacent Texas is *colima* (from *colimaitl*, *colli*, man, technically uncle, *maitl*, hand or arm, Náhuatl, Nuevo León, Tamaulipas, Chihuahua). The reference to a man's hand is not clear, but the wide distribution of the name and its application to the Mexican state of Colima indicate its historical importance. The Aztec glyph for *colima* was a man's arm and hand (Santamaría 1959).

The importance of the wood among indigenous people and early Europeans is evident in the genus name originally applied by Mark Catesby in the 1730s and then formalized by Linnaeus in 1753—*Zanthoxylum*, or yellow wood. Not only is the wood colored, but a yellow dye is made from several species. The color of the wood is inherent in the names *palo mulato* (mulato tree, Jalisco), *pine jaune* (yellow pine, Haiti), *pino rubial* (blond pine, Dominican Republic), and satin wood (Bahamas). Other traits are noted in bastard ironwood (USA), and *correosa* [*corriosa*] (flexible, Texas).

To the Creeks *Z. fagara* was *tofvske* [*tofaskin*] (*eto*, tree, *fvske*, sharp), and to the Seminoles *caháhtí* (Mikasuki). The Mikasuki name was considered a simple term by Sturtevant. They used the wood for bows and arrows (Sturtevant 1955).

The people of Yucatan have several names for *Z. fagara*, but there is no clear relationship between uses and names. Their name *xik-ché* [*xuc-che*, *xuché*] (*xik*, wings, *ché*, tree, Maya) surely refers to the winged rachis. Two other names are related, *tanka-ché* [*tamcaz-che*, *tancas-che*, *tancaz-che*] (*tankas*, something round, *ché*, tree, Maya) and *uolé* [*wolé*] (*uole*, something full, Maya). The apparent relationship to use is for preventing flatulence (Morton 1981). Elsewhere in Mexico and Guatemala a bark decoction is considered sudorific and a stimulant to both arteries and nerves (Morton 1981). *Zanthoxylum fagara* also has been used to treat syphilis.

The most restricted species in Florida is *Z. flavum*, known from the Keys. Elsewhere this species grows in Bermuda, the Bahamas, and from Cuba to St. Lucia; then it is disjunct to Bonaire. *Zanthoxylum flavum* shares names with several other species, including *espinillo* [*espinilla*] (little spiny one, Dominican Republic), Hercules's club, satinwood (USA, Bahamas, Puerto Rico), yellow prickly ash (USA), yellow sander (Jamaica, Puerto Rico), and yellow-wood [heart] (USA). Some names related to other species are *acetillo* (little oily one, Cuba, Puerto Rico), *bois a plans* (spiny tree, *plans* a variant of *épines*, French Antilles), and *kalabari* (maybe from *colibrí*, hummingbird, Bonaire).

This tree also has some unique names. Probably because of the pinnately compound leaves, it is *bois noyer* or simply *noyer* (walnut tree, Guadeloupe). However, the most unusual name is *misimieu* [*musimieu*] (Haiti). *Mise* means to put or to place an object in a chosen location. *Mieux* in French means "the best." Therefore, the name means "the best place to put this plant that will silence you if you trespass on my property." Boundary marking is not a use recorded elsewhere.

Chemicals in *Zanthoxylum* are resins, volatile oils, tannins, alkaloids of the benzophenanthridine-type (chelerythrine, nitidine) and aporphine-type (magnoflorine), with both considered subtypes of the benzyltetrahydroisoquinoline-type. *Zanthoxylum* also contains berberine, lauriflorine, mannoflorine, and lignans (sesamin and asarinin) (Fish and Waterman 1973, Fish et al. 1975, Morton 1981, Hocking 1998, HealthLink Online Resources 2000, E.Eich, personal communication, Sept. 2003). At least some of the alkaloids of the benzyltetrahydroisochinoline-type exhibit local anesthetic effects. Coumarins (dipetaline, alloxanthoxyletin, xanthoxyletin, and xanthyletin) are present in *Z. americanum* but absent from *Z. clava-herculis* (HealthLink Online Resources 2000, Ju et al. 2001).

Poisoning of livestock has resulted from animals eating *Z. clava-herculis* (Bowen et al. 1996). Both coumarins and lignans have shown inhibition of human leukemia cells (Ju et al. 2001). Chemicals from other species are amoebicidal and giardicidal (Arrieta et al. 2001), anthelmintic (Navarrete and Hong 1996), antifungal (Ngane et al. 2000), antimalarial (Gessler et al. 1994), antimicrobial and cytotoxic (Islam et al. 2001, Nissanka et al. 2001), antinociceptive and antidiarrheal (Rahman et al. 2002), have antiplatelet action (Chen et al. 1995, Sheen et al. 1996, Tsai et al. 2000), and have antispasmodic, leishmanicidal, and trypanocidal activity (Bastos et al. 1999, Ferreira et al. 2002, de Moura et al. 2002).

Temperate northeastern foresters Harrar and Harrar (1946) simply wrote “none” for “Importance” for *Z. fagara*. The many people around the Caribbean, who still use tropical species, were surely astonished to learn that their wood, spice, and medicine source had no value. Academics too often ignore other worldviews.

## **Zea**

(Linnaeus reapplied the old Greek name *zeia* or *zea* for some cereal grass, now unknown, to this important New World food plant; akin to Akkadian, *se’u*, grain)

corn (an old Germanic word, meaning a grain or seed; cognate to Old Frisian *korn*, Old Saxon *corn*, Gothic *kourn*); Indian corn; *Turkische corne* (Turkish grain, German, cf. Turner [1548] 1965); Turkish grain [Turkish millet] (cf. Turner [1548] 1965); *Welchkorn* (foreign grain, German)

maize (from the Taino *maisi* or *majisi*); *maïs* (French); *Mais* (German); *mais* (Italian); *maíz* (Spanish); *me* (Creole for *maïs*, Trinidad); *milho* (from Latin *milium*, millet, Portuguese)

***Zea mays*** (from the Taino name, *maisi*)

*à?ù* (Paya, Honduras); *af* (Guatuso, Costa Rica); *ai* (Rama, Nicaragua)  
*abati* [*abaty*, *abatij*, *ubatim*] (contraction of *abatinga*, from *aba*, hair, *tinga*, white, because of the white silks, Tupi, Brazil ca. 1550, Paraguay)  
*abo* [*holaba*, *tapolaba*] (Timucua)

*Agwe’la* (the “Old Woman,” a name used in prayer formulas alluding to the origin legend of corn appearing from where the body of a woman was buried, Cherokee)

*aspî* [*aspee*, *aspeen*] (Mikasuki); *cassî* (Koasati); *chassi* (Alabama); *vce* [*v’ce*, *acî*, *atsche*, *atchee*] (Creek, Muskogee; cf. Simmons [1822] 1973)

*atce’ki* (Ofo)

***Zea mays*.** From Fuchs 1542.

*awasi* (Carib, Suriname); *awási* (Garífuna, Nicaragua)  
*aya* (Miskito, Nicaragua)  
*carracony* (Algonquin, Montreal in 1535); *chasquen* [*chasqueen*,  
*chassqueen*] (Delaware)  
*ha'-ba* (Osage); *hahka* (Tunica); *wagmiza* (Lakota); *wahaba* (Omaha-  
Ponca)  
*ik* (Cabécará, Bribri, Costa Rica); *ip* (Térraba, Costa Rica)  
*ixim* (Maya, Yucatan, Belize); *eem* [*em*] (Huastec, San Luis Potosí)  
*ku la* (black maize, Tarahumara, Chihuahua); *ku mi now* (yellow  
maize, Tarahumara, Chihuahua); *ku Tow* (white maize, Tarahumara,  
Chihuahua)  
*ku's* [*kus*, *kush*] (Catawba)  
*mandamîn* (good berry, Potawatomi); *mahta'min* [*mahta'minak*]  
(Plains Cree); *manda'min* (cognate with *mano'min*, their name for wild  
rice, *Zizania palustris*, Ojibwa)  
*marishi* (Arawak, Suriname)  
*mopj* (Jicaque, Honduras)  
*necoum* [*neshoum*] (Atakapa)  
*onèhha* (Onondaga)

*osapa* (cited by some as “maize,” but correctly the maize “field,” Choctaw)  
*pe* (Chocó, Panama)  
*poketawes* [*pocuntavhca*, *pohcuwtoah*, *poketaws*, *pocuttawes*] (Powhatan, Virginia); *pagatowr* (Carolina Algonquians)  
*ru+krá* (Brunka, Costa Rica)  
*sara* (Quechua, Peru)  
*selu* (Cherokee)  
*tanchi* [*tonche*] (Choctaw)  
*tawmey* (Shawnee, fide Edgar 1891)  
*tsot?o’* (Yuchi)  
*tuùpevu* (Hopi)  
*yek’* [*ye’ki*] (Biloxi)  
*yokotana* (Arawak, Suriname)

I grew up in the land of the Chickasaws—western Kentucky. Bernard Romans ([1775] 1961) was among the first to record that Chickasaws claimed the territory north to where the Mississippi joins the Ohio River, and east to the confluence of the Tennessee and Ohio Rivers. Until late 1818, this region was west of the United States, and Kentucky ended on the east bank of the Tennessee River. Then, through promotion by Andrew Jackson, the land was obtained by a treaty between the United States and the Chickasaw Nation on October 19, 1818. After that, the area became known as the “Jackson Purchase.” I recognized early that southeastern use of maize was a prominent feature of the region’s culture.

My introduction to the cultivation of maize was helping my father plant garden plots. He “hilled” the planting site; small mounds of earth were raised with a hoe and the kernels planted in their loosened tops. Beans (*Phaseolus vulgaris*) were planted with maize seeds so their stems could grow up the cornstalks, and he pulled suckers (lateral stems) from the base of the stalks. All of those techniques were used by south-eastern tribes (Hudson 1976).

When sweet corn was harvested, we ate it roasted on the cob, another indigenous method. The Alabama called them *chassapalyi* (*chassi*, maize, *apayli*, roast), the Choctaw *tanch nipasha* (*tanch*, maize, *nipasha*, roasting ear), or *tanchi hiloha* (*tanchi*, maize, *hiloha*, thunder), and to the Creeks they were *vce lowvcke* (*vce*, maize, *lowvcke*, soft). Capt. John Smith and Strachey wrote of this method among the Algonquians in Virginia in the 1600s (Swanton 1946). In the same region, Robert Beverley wrote in 1705, “They delight much to feed on Roasting-ears; that is, the *Indian Corn*, gathered green and milky, before it is grown to its full bigness, and roasted before the Fire, in the Ear.”

Our daily bread when I was young was corn bread. It was only when I was in grade school that “light bread” (wheat bread) became a daily commodity. For special treats, my mother made what she called *tamales* (from *tamalli*, Náhuatl). Yet, her method was intermediate between the Chickasaw and Mexican preparation. She filled the cornmeal dough with cooked meat instead of the beans, sunflowers, or hickory nuts the Chickasaws would have used. However, she tied the ends of the corn husks covering the *tamale*

before boiling it—a decidedly Muskogean method (Byington et al. 1915, Hudson 1976, Kimball 1994).

Perhaps because we lived in the borderlands between the “South” and the “North,” we did not eat grits. My uncle had never seen grits in his life until, in his 60s, he visited us in Florida and was served the Creek preparation in a Georgia restaurant. Of course, the Creeks and their relatives put bear oil instead of butter on their grits, but otherwise the dish is unchanged (Hudson 1976).

No one in Europe had seen maize before Columbus found it being cultivated by the Taino people in the Caribbean in 1492 (Jane and Skelton 1960, Hawkes 1998). Benzoni’s *History of the New World*, published in 1572, affirmed that Columbus brought seed of maize back to Spain in 1493 (Hedrick 1919).

Hedrick (1919) wrote that Columbus recorded *Zea* and called it *maiz* while he was in Cuba during November of 1492. My translation by Jane and Skelton (1960) does not have that passage, and Hawkes (1998) did not find it either. However, Columbus wrote on 16 October that the island he called Fernandina (Long Island, Bahamas) “is very green and flat and very fertile, and I have no doubt that all the year they sow and reap Indian corn.” Unhappily, Jane and Skelton (1960) did not include the Spanish word used by Columbus.

Maize was cultivated in Seville in 1500 and near Avila in 1530 (Hawkes 1998). The grass was introduced from Cádiz into northwestern Portugal in 1520 (Hawkes 1998). Subsequently, it spread through Europe and was mentioned by Fuchs (1542), Monardes in 1569 (Monardes [1577] 1925), and Clusius in 1576 (Hawkes 1998).

By the time Fuchs (1542) wrote about maize, the knowledge that it came from the New World had been lost. That confusion is said to have begun in the 1530s (Hedrick 1919). Fuchs called it *turcicio frumen to* (Turkish corn), but he also said it was *miliun indicum* (Indian millet). Calling it “corn” in 1542 seems today like the obvious thing to do because that name is applied in most English-speaking countries. However, “corn” was an old word for wheat (*Triticum*), and Fuchs was really comparing the new grain with that old familiar food. Germans knew maize as *Türckish korn*, with the related Dutch *torckish coren* in use by 1549. The French said *bled sarrazin* in 1549, *blé turquois* in 1550, and *blé de Turquie* in 1551. Italians said *formento turckischo* by 1551, and Spanish *trigo de Turquía* by 1557. Those were really just different words for what the English speakers called it, like Henry Lyte’s “Turkish or Indian wheate” in 1578 and John Gerarde’s “Turky wheate” in 1597 (Meyer et al. 1999).

It fell to Pedro Mártir de Anghiera in 1493 to record, “the panicum of this country...they call *maizim*” (Hedrick 1919). Oviedo in 1534–1537, and Bartolome Las Casas in the 1550s also record the Taino name for these grasses. Oviedo wrote, “*a esta clase de trigo le Lllaman maiz*” (this type of wheat they call *maiz*). Las Casas (in the 1550s) said, “*Sembraban y cogian dos veces al trigo, el grano que llamaban mahiz, no para hacer pan del, sino para comer*” (Twice they planted and harvested the wheat, the grain that they call *mahiz*, not to make bread of it, but to eat). Coll y Toste (1972) suggested that the original word was probably *majisi*, since the “h” did not exist in Taino.

Bartolome Las Casas wrote, “*El indo-antillano comia el maiz tostado, el indio de Tierra Firme hacia pan de maiz, moliéndolo en un mortero de piedra y haciendo tortas llamadas arepas*” (The Antilles Indians eat maize toasted, the Indians of the mainland

make maize into bread, grinding it in a pestle of stone and making cakes called *arepas*) (Coll y Toste 1972). *Arepas* is still the name of the corn cakes in Venezuela.

The first historical record of maize in Florida was from the 1528 Pánfilo de Narváez expedition; de Soto also found “*maes*” in 1540 (Hedrick 1919). Jean Ribaut found maize among the Timucua in north-eastern Florida in 1562, but also used its Taino name *mahiz*. All of the historic Florida records are from Timucuan and Choctaw tribes. There was no maize grown by the Glades tribes in spite of Sears’s (1982) claims to the contrary. I studied his slides made from the Fort Center site and showed Mary Eubanks photographs of the grains. We both conclude that Sears mistook *Tripascum* pollen for maize.

We retain perhaps more of the indigenous methods for eating maize than any of the other plants used by American tribes. In 1753, Dumont de Montigny wrote of the Natchez in what is now Mississippi. He first noted that there were three kinds of corn being grown, and then continued, “They can be prepared in 42 styles, each of which has its special name. ...It is sufficient to inform the reader that there is made of it bread, porridge [*bouillie*], cold meal [*farine froide*], ground corn [*farine grôlée*], smoked-dried meal or meal dried in the fire and smoke, which when cooked has the same taste as our small peas and is as sugary. That is also made which is called gruel [*grut*], that is to say that having beaten and pounded it for some time in a wooden mortar, along with a little water, the skin of envelope with which it is covered is removed. The grain thus beaten and dried is transported to great distances and keeps perfectly. The fines of that left behind is used in making hominy [*sagamité*, an Algonquian word], which is a kind of porridge cooked with oil or meat” (Swanton 1946). See Crawford (1978) and Drechsel (1997) for a discussion of the incorporation of the Algonquian word *sagamité* or *sacamité* into not only Louisiana French, but also into the Mobilian Jargon.

Smith (1992) noted that more than 90 dishes of maize were made in the southeast. So, it is an oversimplification of actual usage, but most of those dishes were variations on four basic preparations for ripe maize. The four preparations were hominy, cracked hominy, bread, and cornmeal.

Hominy was made by soaking the grains in lye from wood ashes until the aleurone, the outermost layer of the grain, was loosened. This covering was then separated from the “popped” starchy interior, the hominy. At least, that is the meaning of the word “hominy” now, but it was not always defined that way. Each tribe had a special term for this preparation—*chassoolbi* (*chassi*, corn, *oolbi*, soaked, Alabama), *vce sokv* (*vce*, maize, *sokv*, hominy, Muskogee), *olbí* (Koasati), and *newada* (Cherokee). To the Choctaw it was *tanlubo* [*tan hlabo*] or *tan-lubona* (*tanci*, corn, *lubo*, round). Siouxan speakers said *a'tcak-bi'ska* or *indaki'* [*in'taki*] (Ofo), *hauni'* (lye hominy, Biloxi), and *ko'tyuki* (Tunica).

Hominy was typically “cracked” before it was eaten. That grinding process was accomplished with a wooden mortar, usually of gum (*Nyssa*), hickory (*Carya*), oak (*Quercus*), or beech (*Fagus*). The pestle, often made of oak or hickory, was about 6 inches in diameter and 5 to 6 feet long. This was narrowed to about 2 inches for four fifths of its length and the remainder was left as a weight at the upper end.

Cracked hominy was made by placing dry corn kernels in a container with water and wood-ash lye. After soaking overnight, the corn was drained and the grains placed in the mortar where the pestle was used to crack them and loosen the hulls. A large flat basket with a shallow pocket on one side was used to separate the chaff. In the South, “cracked

hominy” came to be called “hominy grits” or simply “grits.” That name “grits” was an English term in use by 1579 for coarsely ground oatmeal. About 1886, the term “grits” was being applied to cracked hominy.

This product of “cracking” also had descriptive names—*chasbotáoka* (*chassi*, corn, *botooka*, ground up, Alabama), *tanchi’ bota’ [tabota]* (*tanchi*, corn, *bota’*, ground up (Chickasaw), *tanchi bota* (*tanchi*, corn, *bota*, ground up, Choctaw), *vce-enfulotkv* (*vce*, corn, *enfulotkv*, ground up, Muskogee), and *selu isa* (*selu*, corn, *isa*, meal, Cherokee). Sometimes it was simply meal, as in *botooka* (Alabama), *bota [botah]* (Choctaw), *hockvte* (Muskogee), *isa* (Cherokee), and *tsukhá* (Yuchi). The Powhatans in Virginia and the Carolina Algonquians called cornmeal *rokohamin* [*äpärunmenan*, *rockahominy*, *rokehamen*] (Gerard 1907, Harrington 1955). Siebert (1975) wrote this phonetically as *rohkahamen*, and noted that the root was */\*lo-xk-/*, soft, with cognates in Cree (*yo.sk-*), Fox (*no-kh-*), Menomini (*no-hk-*), Ojibwa (*no-kk-*), and Penobscot (*nohk-*). Penobscot speakers called it *nòhkhamen* (parched corn meal). Siouan people said *ye’ nupxi’* (fine corn, Biloxi), *atcék anapha’si* (Ofo), and *ha’hkiri* (*ha’hka*, corn, *ki’ri*, ground, Tunica).

Breads were made by frying, baking, or boiling. The hominy was pounded into fine meal and mixed with water to form batter, in Alabama *olmo* (mixed with water) and in Chickasaw *paska toba* (*paska*, bread, *toba*, becoming). A thin batter was made into “fritters” by cooking in a flat-bottomed pot with bear grease. Thicker batter was made into loaves or “pones.” The loaves were baked on thin, broad stones placed over or beside the fire, or in a flat-bottomed pot with another inverted over it and the two covered with hot coals. The Yuchi called those cakes *kánla*.

This cooking method lives on in the eastern United States, where the food is called Johnny cake [Johnnycake, jonnycake], journey cake, and Shawnee cake. The name “Johnny cake” was in use by 1739, and might be from *jonakin* (American Heritage 2000). Another view is that early American settlers ate this on long trips, and that gave rise to “journey cake,” which then produced “Johnnycake.” The third possibility is surely related to the indigenous northeastern “chief” named “Journeycake” (Mitchell 1895). Since the American Heritage dictionary gives no etymology of *jonakin*, the origin is unresolved. Johnny cake is now a New England specialty, especially in Rhode Island, where it is celebrated by the “Society for the Propagation of Johnny Cakes.” The name “Shawnee cake,” however, reveals that its origin was not just local. The Shawnees lived, among other places, in southern Illinois, Indiana, and north-central Kentucky (Grosvenor et al. 1972, Callendar 1978).

The Usquepaugh, Rhode Island, “Johnnycake Festival” features cakes made of white flint corn (because of the hard starch). Outside New England the name Johnnycake is best known in the Upper Midwest, but the food itself is most popular in the South and South Midland states, where it is known as ashcake, batter bread, battercake, corn cake, cornpone (see “pone” below), or hoecake. The color of the cornmeal, the consistency of the batter, the size of the cake, and the cooking method vary from region to region. For example, an ashcake, according to one Georgia *aficionado*, is “made by wrapping cornbread batter in cabbage leaves and burying it gently at the back of the fireplace.” As “hoecake” suggests, the bread was supposed to be cooked by field hands on the metal part of their work instruments. Surely, they used the hoes only as a spatula to insert and remove the bread from the fire—otherwise, how did they keep the handles from burning?

The Choctaw dish *paluska holbi* (*paluska*, bread, *holbi*, within) was made by wrapping the loaves in rehydrated dried corn husks, tying the ends and middle with a strip of husk, and baking them in hot coals. To the Alabama, this was *paspá hokfi*, the Muskogee said

*aya?a.*

*taklike ofi*, and the Cherokee *gadu*

The Creeks made *chuto-ahake* (*chuto*, bread, *ahake*, hard) by forming the batter into doughnut shapes, baking, and then drying the loaves in the sun until they were as hard as wood. These *chuto-ahake* were strung on cords for later use, but had to be stewed to make edible. This was *paska kallo* (Chickasaw) and *tvklike takv'cwe* (Muskogee).

Sometimes the batter was made like *paluska holbi*, but boiled instead of baked. To the Alabama, this dumpling was *chassoochiika* (*chassi*, corn, *chiika*, made, Alabama), and their relatives said *hassabonká* (Koasati), *paska alhfola* [*paskalhfolá*] (*paska*, bread,

*aʔfola*,

dumpling, Chickasaw), *banaha* (Choctaw), and *tvklike-óme* (*tvklike*, bread, *óme*, like, Muskogee). The Cherokee knew them as *digalvnhí*. Variants of this included the Choctaw *tanch hiloha palaska* (*tanch*, maize, *hiloha*, thunder, *palaska*, bread), *tanch hotokbi palaska* (*hotokbi*, moist), or *naksakawa*. There was also the traditional boiled blue corn bread dumpling often eaten with salt pork grease. That blue dumpling was called *paspokchakko* (*paspá*, bread, *okchakko*, blue, Alabama), *paska okchamali* [*paskochamali*] (*paska*, bread, *okchamali*, blue, Chickasaw), and *cvtvkhv* (Muskogee). A variant was *paspoochiika* (*papa*, bread, *chiika*, made), which was made from cornmeal mixed with a little flour and water, shaped into patties, boiled, and served with bacon grease (Sylestine et al. 1993).

These preparations are almost identical to the Mexican preparation of *tamales* (*tamalli*, Náhuatl). The cooked loaves could be eaten fresh or dried for later use. Instead of wrapping the batter in husks, they sometimes dropped balls or flat cakes of it into boiling water to make a corn dumpling. This dish remains as “hush-puppies,” although they are deep-fried rather than boiled as the native Americans cooked them.

Southeastern people referred to cornmeal as “cold meal.” This was what Frenchman Dumont de Montigny called *farine froide*. Dry corn was soaked overnight in warm water. The kernels were parched in a pot of ashes until brown, then pounded in the mortar until they became fine meal. A fanner separated the hulls (*mayeta*, to fan corn, Muskogee;

*[taʔpak]*,

*talhpak* winnowing basket, Chickasaw; *ufko*, fanner, Choctaw). To store the meal for longer periods, it was dried further over a smoky fire. Originally, southeastern tribes had a variation of the cold meal (Romans [1775] 1961, Swanton 1946). Corn that was shelled when ripe but not dry was used to make *bota lanshpa* [*bota lanschpa*] (heated corn, Choctaw). This distinction was lost on Europeans and seems to have been abandoned later by the tribes (Campbell 1959).

To indigenous people, cold meal was *atschehotowaw* (*atsche*, maize, *hotowaw*, cold, Creek, cf. Simmons [1822] 1973), *botooka kasahka* (*botooka*, ground up, *kasahka*, cold, Alabama), *hot ah kapussa* or *tan̄sh fotoha* (*tan̄shi*, maize, *fotoha*, ground up, Choctaw),

*hockvte kvsvp'pe* (Muskogee), *tashfoloha'* [*tashfolowa'*] (*tanchi'*, corn, *foloha*, ground up, Chickasaw), or *gawi sida* (Cherokee). Virginia Algonquians said *yiketehamun*.

*Botah kapussa* was eaten dry or made into gruel by adding one portion of meal to two of water. Their gruel preparation was a variation of what the Mexicans call *atole* (from *atolli*, Náhuatl). This may be what the Alabama called *afolka*, the Chickasaw *tafolá*, the Choctaw *tansh lakchi* (maize dregs) and *tanfula*, and the Muskogee *nerkvce* (small seeds or grits).

In addition to the name maize, the grass has resulted in other contributions to the English language, including hominy, pone, succotash, and sofkee. "Hominy" is a Virginia Algonquian word first recorded by Capt. John Smith in 1629. He wrote, "Their servants commonly feed upon Milke Homini, which is bruized Indian corne pounded, and boiled thicke, and [hickory] milke for the sauce." Bartram ([1791] 1958) wrote that hickory milk "is an ingredient in most of their cookery, especially homony and corn cakes." Elsewhere Smith called it *Ustatahamen* (from *ûsekkutehemén*, crushed by pounding), William Strachey called it *Vsketehamum*, and Catesby (1734–1747) called it *roccahomony* (Mahr 1955b).

In 1634, another comment on Maryland tribes was that "Their ordinary diet is Poane and Omine, both made of corne." In 1772, John Josselyn wrote of the people of New England, "They beat the corn in a mortar and sift the flower [*sic*] out of it: the remainder they call Homminey." The first record of a dish called by the name in Florida was by Jonathan Dickinson in 1699, when he wrote, "Our chief dyet was Hommeney." As Swanton (1946) pointed out, all of these hominy preparations are equivalent to *pinole* (from Náhuatl *pinolli*) consumed by the Aztecs of Mexico.

The etymology of "hominy" is uncertain, but most sources compare it to Algonquian words like Natick *minne*, and Narraganset *min*, grain. Siebert (1975) glossed the Powhatan word as *apohomin*, "grain of parched corn." He based that on Strachey's *aphohomins*, and both have as their root */\*apw-/*, heat, */\*-ahw-/*, instrument, and */\*-min-/*, grain. In other words, hominy was parched ground grain, just as he translated it. The prefix */\*apw-/* has been compared with Narraganset *appoon*, to bake. This *appoon* of the preparation "hominy" contributed the next loan-word.

*Pone* (from *âpân*, baked, Powhatan) is a word from Virginia first recorded by Capt. John Smith in 1612. Speaking of their foods, he wrote of them "eating the broth with the bread which they call *Ponap*" Strachey also recorded the word as *apones*, *appoans*, and *apetawh poan*, in 1612 (Harrington 1955). Siebert (1975) noted that phonetically this was *aponas*, "loaves of bread." The cognate in Menomini is *apuan* and in Penobscot *âpan*. The word is related to Fox *aponewa* (he makes a roast for him) and Cree *apwan* (roast of meat). By 1716, Robert Beverley wrote, "The bread in Gentlemen's Houses, is generally made of Wheat, but some rather choose the Pone, which is the Bread made of Indian Meal...so called from the Indian name *Oppone*"

"Succotash" is another Algonquian contribution to English, and it was in use by 1751. The word is akin to Narraganset *msakwatas* or *msiquitash* and consists of beans and corn cooked together. James Fenimore Cooper, in his *The Last of the Mohicans* of 1826, spelled it "*suc-ca-tush*"

John Bartram called one dish he ate "Indian corn soup, or thin homony" in 1751. Another reference in 1771 compared hominy to "rice-pudding." Those dishes were probably identical to what the Koasati called *cawáhka* [*cassapáya*], the Alabama

# hořka,

the Creeks and Muskogees *sáfke* [*osařkv*, *safkv sofkee*, *sořki*], the Choctaw *tanřula* [*tan řula*], and the Cherokees *ganoheni*. This dish is cracked hominy cooked with water and enough wood-ash lye to turn it light yellow (Hudson 1976).

The Yuchi knew *sáfke* by what is probably the cognate word, *tso'ci* (sun fluid). According to Yuchi legend, a woman of the ancients cut a hole in the sky. From this hole there flowed a liquid. She tasted it and found it good. So, ever since, her people have called it “sun fluid” (Speck 1909).

This “sofkee” was southeastern hospitality food, and visitors were expected to help themselves to a bowl using a spoon kept alongside. Anyone who failed to eat a little was considered impolite (Hudson 1976).

Another dish was known as *sappaun* (Delaware), said to be a “hasty pudding” made from maize in 1654 (Hedrick 1919). The Powhatan in 1612 used the cognate *aspan* (Harrington 1955). Later, Catesby (1743–1747) also referred to a “*Mush...made of the meal, in the manner of hasty-pudding.*” This was probably the same dish that Dumont called *bouillie* (porridge) in 1753 among the Natchez. This became “samp” among the colonists.

Moerman (1998) wrote simply that the Seminoles used maize seeds as food, but Bartram ([1791] 1958) gave more details. During his visit to the Alachua Savanna (present-day Payne’s Prairie near Gainesville), the Seminoles served Bartram “venison, stewed with bear’s oil, fresh corn cakes, [hickory] milk and homony, and our drink honey and water, very cool and agreeable.” When Bartram was at Fort Picoleta near Fort Augustine, he remembered that the Seminoles also used acorn oil (*Quercus virginiana*) in preparing hominy.

In addition to the food they prepared, Campbell (1959) recorded a unique storage method. Gideon Lincecum wrote that the Choctaw would “gather corn, dry it in the sun thoroughly, then lay it in small lots in a dry place, cover it with a coat of dry grass, then a thick coat of good clay mortar well mixed with grass. When it was completed, the numerous little piles of two or three baskets of corn, each covered and arranged side by side, looked like a big mud dauber’s nest. In this manner they could keep their corn sound and sweet from year to year.”

The Cherokee made corn husk dolls (Hamel and Chiltowsky 1975). If these had any religious significance, no reference has been found. However, among the Iroquois, corn husks were part of the Husk Face Society, which they called

# katsiřsa?

(Cayuga, Seneca),

# hatsiřsa?

(Onondaga), and *katiřsq* (Mohawk) (Trigger 1978). The tutelaries of the society were agricultural spirits. Individuals wearing these masks usually appeared in the Midwinter ceremony, and sometimes served as messengers for the False Faces. However, the Husk Face and False Face were two different societies, appeared separately, and performed cures. If anything like this existed among southeastern tribes, no records have been located.

If the southeastern people were at all like those in Mexico, they had multiple uses for corn cobs. They called them *chassapi* (Alabama), *pahoha* (Choctaw), *talv'pe* (Muskogee), and *selu uda* (Cherokee), all meaning “corn stem.” Powhatan said *okishec* [*okiicshec*],

which Siebert (1975) rendered as *ohkit*, or plural *ohkicis*. He found cognates in Cree as *oskiciy* and Ojibwa *okkic*, both of which mean pipe stem. He concluded that the ancestral (Proto-Algonquian) word was /\**wexkicyi*/ and that it meant spike, spadix, inflorescence.

Since many of the archaeological cobs are charred, it seems likely that they were sometimes used as fuel (Eubanks 1999, 2001). In Mexico, I often noticed corn cobs stored on the roofs of houses. Finally, Bob Bye reminded me that there was another use for them—as substitute toilet paper. I had heard of that as a joke when growing up, but I never really believed anyone would use that rough item on such a tender spot. Given the frequency of the allusion to its use in the South, indigenous tribes and settlers had the same use as the Mexicans.

The only record of medical use found for the southeast was among the Cherokee. They used the “smut” from the plant (*Ustilago maydis*) as a salve, an infusion of the silks for kidney stones, and ate the parched grains for “long wind” (i.e., endurance) (Hamel and Chiltoskey 1975). However, the uses as salve and for kidney problems were widespread in tropical America (Morton 1981). Murphee (1965) found residents of the Panhandle using a tea of corn husks to treat measles and congestion and to lower fevers; they also smoked corn silk to cure sore throat. Foster and Duke (1990) and Duke et al. (2002) confirm that corn silks (technically, the styles) have long been used as a diuretic, and as treatment for cystitis, gonorrhea, gout, and rheumatism. Experiments have established that maize has diuretic, hypoglycemic, and hypotensive activity. It is also known that the seeds contain allantoin, a cell-proliferant, wound-healing substance.

### ***Zephyranthes*: Rain Lilies**

(Derived from *zephyros*, the Greek god Zephyr was the west wind that reawakened nature each spring, and *anthos*, flower)

***Zephyranthes atamasco*.** (left) From Robert Morrison (1699), who called the herbs *Lilio narcissus indicus pumilus monanthos walbus*. (right) From Britton and Brown (1896), who

used Linnaeus's name *Zephyranthes atamasco*, with a more technical drawing.

When the first Europeans arrived in the New World, they viewed all "plants" as potential "herbs." For example, in the late 1500s and early 1600s, a person could find 300 to 400 medicinal and culinary herbs in a single English garden. Virtually none was "just" decorative. All levels of society were permeated by this obsession because people's health and food depended on their knowledge of plants. Among the many species that Europeans considered medicinal are "Lilies," "Amaryllis," and "Crocus."

One of the early New World visitors discovered another "lily" growing in the coastal regions of what is now the State of Virginia. This lily became the first of the rain lilies known to the world (Kral 1983a, Meerow 1984, 1985).

This rain lily received its current name, *Zephyranthes atamasco*, in 1821 from William Herbert (1778–1847), a British politician and botanist who later became active in the Church of England and was dean of Manchester. However, European knowledge of these herbs began long before that. The first record of the plants in Europe seems to have been with John Parkinson who called them *Lilio Narcissus virginicus* (Daffodil lily from Virginia) in 1629. Then, in 1696, Leonard Plukenet called them *Lilio narcissus liliflorus carolinianus* (Daffodil lily from Carolina with lily flowers). Catesby (1731–1732) reverted to the Parkinson name.

Parkinson cited the common name in Virginia as *attamusco*. Although Mish (1988) wrote that the word appeared in English in 1743, it actually appeared earlier. *Attamusco* was used by Parkinson in 1629, Plukenet in 1696, and Morrison's *History of Plants* published in 1699. Catesby (1731–1732) also wrote "The Attamusco Lily." Mish (1988) said that *attamusco* meant "it is red," but Gerard (1907) contended that it came from *ätamäsku* (*ätam*, under, *äsku*, grass. Virginia Algonquian).

Linnaeus ([1753] 1957) picked up the common name and called the herbs *Amaryllis atamasco*. As more kinds of "lilies" became known to Europeans, they realized that several genera were involved. Now *Zephyranthes* contains 40 species in the warm-temperate and tropical parts of the Americas (Meerow 1984, 1985, Mabberley 1997). Florida has three species—*Z. atamasco*, *Z. simpsonii*, and *Z. treatiae* (Wunderlin 1998). Only information on *Z. atamasco* being used has been found, but perhaps all three were part of the ethnoflora.

When John K. Small wrote his *Manual of the Southeastern Flora* in 1933, he recorded common names for the four *Zephyranthes* he found. He and others called them amaryllis, atamasco-lilies, Easterlilies, fairy-lilies, rain-lilies, stagger-grasses, and Zephyr-lilies. To Bahamians they are crocus or snowdrop. Colombians think they look like the *jacinto* (hyacinth). Cubans call them *brujita* (little witch); Puerto Ricans and Dominicans say *duende* (little devil) or *adelfa* (Puerto Rico). Haitians say they are a *tulipe* (tulip), while they are *petit lis* (little lily) or *lissavane* (savanna lily) in Guadeloupe and Martinique.

These common names tell us several things about what people think of the plants. First, Europeans and their descendants in the Americas saw resemblances between Old World plants (lilies, crocus, amaryllis, snowdrops, hyacinth) and those found in the New World. Instead of incorporating new names for the American plants, sometimes they simply transplanted old ones for them. At other times, the newcomers adopted indigenous

names. The specific name *atamasco* and the common name atamasco-lilies are derived from *attamusco* used for the plants by speakers of an Algonquian language in Virginia. *Atamasco* is a reference to where the plants grew.

The generic name of rain lilies speaks of plant biology. *Zephyranthes* is an allusion to their tendency to flower suddenly after a spring or summer downpour, appearing as if by magic from what had seemed to be grass leaves. The names *brujita*, *duende*, fairylilies, rain lilies, and Zephyr-lilies all refer to the abrupt emergence.

Stagger-grasses alludes to the symptoms shown by cattle and horses when they graze on *Zephyranthes* (Gerard 1907). Indeed, *Zephyranthes* contains a cock-tail of alkaloids including poisons (e.g., lycorine, glycosides, pancratistatin) and antitumor agents (Krishna Rao 1969, Kobayashi et al. 1977, Nakayama et al. 1978, Krishna Rao and Krishna Rao 1979, Petitt et al. 1984, 1990) Ghosal et al. 1985, 1986, 1987, Kojima et al. 1998). Hedrick (1919) and Yanovsky (1936) say that the bulbs of Atamasco-lily were eaten by the Creek Indians in time of scarcity, but that would be risky. Perhaps stagger-grass was made acceptable by roasting, as is *Z. Candida* in tropical America (Hocking 1997). Seminoles also used *Zephyranthes* as an analgesic against toothache (Small 1933). Other species have been used to treat diabetes, to reduce fevers, in poultices against abscesses, against colds, coughs, and tuberculosis, and to treat external infections (Eldridge 1975, Morton 1981, Ayensu 1981).

*Zephyranthes* species are under different controls on flowering, and there sometimes seems to be no rhyme or reason as to when blossoms appear (Broyles and Watt 1991, Mori and Imanishi 1997). Less is known about the introduced and cultivated species, but many are stimulated to flower by fires, mowing, and spring or summer rains. When fires burn throughout our remaining pine flatwoods, the rain lilies are among the species responding. Even though the timing of the rains varies, if the temperatures change enough the plants are stimulated into flowering. Mowing is an artificial “fire” from the plant’s view. When these herbs are in lawns, roadsides, or pastures, mowing causes them to flower in the “wrong” season, especially if the soil is moist enough. Yet, Florida natives are especially sensitive to Zephyr when he starts the spring rains, which then bring the rain lilies to their peak.

### Old World Relatives

**Amaryllis**—This word appeared in the Greek poetry of Theocritus (310–250 B.C.), and was used later by Latin poets Ovid (43 B.C.-A.D. 18) and Virgil (70–19 B.C.). The original name was of a Greek country girl or shepherdess. By 1637, herbalist-physicians had begun using “amaryllis” for liliaceous plants. Finally, Linnaeus started applying it to relatives of *Hippeastrum* (common name amaryllis) in 1738. As a genus, *Amaryllis* is restricted now to *A. belladonna*, the belladonna lily from South Africa. However, by 1753 this African species was already well known in Europe, the Caribbean, and South America.

**Crocus**—Another Greek classical name, *krokos*, has cognates in Hebrew (*karkom*), and Arabic (*kurkum*). Crocus was a young Greek shepherd who fell in love with Smilax, a shepherdess. She ignored him, and when he died of a broken heart, the gods changed him into a flower bearing his name. *Crocus* spread in Latin northward from the Mediterranean and became part of Old English (*croh*) and *kroch* in Irish and Gaelic.

“Crocus” turns out to be two botanical genera in different families. *Crocus sativus* (Iridaceae, iris family) is the source of saffron (from Arabic *za'faran*). Although originally used as a reddish dye, saffron eventually became the signature ingredient in certain Mediterranean foods. Then it was discovered that those who used the seasoning had fewer cardiovascular problems than their neighbors. Not only does the spice reduce heart and other circulatory problems, but it is also the richest known source of vitamin B<sub>2</sub> (riboflavin).

The other “crocus,” *Colchicum autumnale* (Colchicaceae), is the source of colchicum (*tinctoria colcichi*), which is used as a pain killer for gout. The active ingredient, colchicine, is an alkaloid that also causes errors in cell division, resulting in doubled chromosomes. Colchicine was first used in plant breeding, and then in treating certain kinds of cancer.

See also *Lilium*.

### *Zizania*

(Adapted from the Greek *zizanon*, a weed of wheat fields)

***Zizania aquatica*.** From Institute of Food and Agricultural Sciences.

***Zizania aquatica*** (of wetlands)

*apetéléwimin* (laughing grains, Penobscot); *matomin* (Capt. John Smith and William Strachey wrote the Virginia Powhatan word *mattoume*); cognates include *mal8min* (Abenaki); *malo-mina* (Miami); *malomin* (Nipmuck-Pocumtuck); *mandamin* (good berry, Potawatomi); *manomeh* (Menomini); *manomin* (Swampy Cree, a loanword from Ojibwa); *manomina* (Fox); *menomin* [*mano'min*, *minomina*, *menomen*] (Ojibwa); *omanomen* (the Menomini tribe, whose name was taken from *omanomen*, rice, and *inini*, people)

*bo'-çu* (Osage); *psin* (Dakota); *sin* (Winnebago); *sinwaninda* Omaha-Ponca)

*folk avoine* (wild or foolish rice, Quebec)

*honoshe* (Choctaw; Bushnell 1909); *aloshommá* (*aló:so*, rice, *hommá*, red, Koasati)

[annual, Canadian, Indian, wild] rice [wildrice]

*riz sauvage* (wild rice, Quebec) *te'ue-u* (Atakapa)

Tuscarora rice (this Iroquoian tribe originally lived in Virginia)

water oats [wateroats]

*widlogouil* (Natchez, fide Du Pratz 1758 in Gilmore 1931)

The chasm between people of the real world and “science” constantly amazes me. Europeans in the scientific community did not know wild rice until after 1743 when it was described by Jan Gronovius from Virginia. The plants as food, however, were known to European visitors in Virginia and the Great Lakes region from at least the early 1600s.

Capt. John Smith, writing in the first two decades of the 1600s, told of the Virginia Powhatans eating the grain. He wrote that it “groweth as our bents do in meadows...seed is not much unlike to rye, though much smaller...this they use for dainty bread buttered with deer suet.”

Later, French explorer Pierre Esprit Radisson wrote of eating the rice before 1660 when he and Médard Chouart Groseliers returned from exploring the *Trots-Rivières*, opening up new territory in the far end of Lake Superior (Allen 1999). Radisson wrote: “Our songs being finished, we began our teeth to work. We had a kind of rice much like oats. It grows in the water three or four feet deep. They have a particular way to gather up that grain. Two take a boat and two sticks, by which they get the ear down and get the grain out of it. Their boat being full, they bring it to a fit place and dry it, and this is their food for the most part of the winter, and they do dress it thus: for each man a handful of that they put in a pot, that swells so much that it can suffice a man” (Radisson in Olson 1963).

Father Marquette in 1673 spoke of the tall grass growing in the rivers and swampy places, which “[t]he Savages Gather and prepare for food in the month of September.” He then described how they shook the seeds from the stems into their canoes, dried it on a grating over a low fire, and trod the grain to separate the chaff.

The grass was so important to dwellers in the Great Lakes region, that early French explorers called one tribe the *Folles Avoines*, although its real name was Menomini. Even the State of Wisconsin may owe its name to *Zizania* (Olson 1963). Although that name is said to come from “an Algonquin river name” (Billard 1974), it probably came from *weese-co-seh*, meaning a good place to live. In other words, a place where wild rice grew.

Another early account of the grass was written by Father Hennepin who, in 1680, ate the grain on the upper Mississippi River and pronounced it better and more wholesome than rice (Hedrick 1919). Finally, Jan Gronovius named the plants *Zizania* Linnaeus ([1753] 1957) accepted his designation as *Zizania*, and added the species epithet *aquatica*.

Not long after receiving a formal Latin name, these grasses were discussed by other explorers. In 1784, Jonathan Carver wrote of wild rice as the most valuable of all the spontaneous productions of the “Northwest” [Great Lakes Region]. Regarding this edible grass, Porcher (1863) continued, “This plant was experimented with by Sir Joseph Banks, by removing it from Canada to England in 1791. At first it could scarcely endure the climate, but gradually improved and became thoroughly acclimated. It became ‘in fourteen generations as strong and as vigorous as our indigenous plant.’ ‘It abounds in all the shallow streams of North America, feeds immense flocks of wild swans and other water-fowl, contributes largely to the support of the wandering tribes of Indians. ... This grain has become acclimated in Middlesex, producing bland, farinaceous seeds, which afford a very good meal.’ ... It would perhaps reward the trouble to experiment with this plant at the South, in order by cultivation to procure a new cereal.”

*Zizania* is a small genus, containing three or four species. While Hitchcock and Chase (1950), Fernald (1950), and Watson and Dallwitz (1992) recognized three species, Kartesz (1994) included four. The difference is whether or not the plants in the Great Lakes region are distinct species or varieties (Warwick and Aiken 1986, Duvall and Biesboer 1988, Reveal 1992b, Terrell et al. 1997). If they are considered distinct species, then North America has *Z. aquatica* (mostly coastal regions), *Z. texana* (Texas), and *Z. palustris* (Great Lakes vicinity). If combined, *Z. aquatica* has priority over *Z. palustris*,

The other species, *Z. latifolia*, grows in Asia, and it too has been considered only a variety of *Z. aquatica*. Young shoots of *Z. latifolia*, known as *kaw-sun*, are eaten in Chinese food to give texture; spores from a smut fungus growing on the plant are used to dye eyebrows and hair (Hedrick 1919). Mats are made from the leaves (Mabberley 1997).

*Zizania texana* has always been a restricted endemic in Texas, confined to the San Marcos River region of Hays County. When Correll and Johnston (1970) wrote the flora of the state, they considered it rare. Now the species is endangered (Poole and Bowles 1999).

Thomas Jefferys wrote in 1760 that the people of Louisiana gathered the seeds and made them into bread (Hedrick 1919). That seems to be only the second record (after Capt. John Smith) of early use by people in the southeast. However, the name “Tuscarora rice” suggests that the grain was also eaten by that tribe in Virginia and by the Powhatans there. Indeed, it was a statement written in the 1860s that probably explains the lack of information about these grasses in the South. Porcher (1863) wrote that, in the opinion of some, *Z. aquatica* “seems destined... to become the bread-corn of the North.” The “bread-corn” of the South was *Zea mays*. Although *Zizania* grew in the southeast, reaching as far west as Texas, indigenous people and then settlers and slaves were accustomed to eating

maize; any other grain was secondary. In Texas, *Z. texana* was eaten like *Z. aquatica* (Hocking 1997), but the rarity of this species has precluded its widespread use.

The grains of *Zizania* were important food to the Dakota (North and South Dakota), Meskwaki (Iowa), Menomini (upper peninsula Michigan), Ojibwa (Ontario), Omaha (Nebraska), Ponca (South Dakota and Nebraska), Potawatomi (lower peninsula Michigan), Thompson (British Columbia), and Winnebago (Minnesota, northern Illinois) (Gilmore 1919, Smith 1933, Olson 1963, Moerman 1998). Maybe the Iroquois also ate it because Yanovsky (1936) indicated that it had been eaten in New York. That is surely an underestimate of its importance because Hedrick (1919) noted that the grass was abundant on the Hudson and Delaware Rivers in New York. At the higher latitudes where there were abundant wetlands, this grass was an important element in the diet of all the tribes (Gilmore 1919, Hedrick 1919). Olson (1963) reminded us that “Bloody tribal wars were once fought for its possession, and those whose lands included strands of it were considered wealthy and insured against starvation and want.”

Lorenz (1981) found that most of the modern commercial rice comes from Minnesota, with smaller quantities from Wisconsin and southern Canada. *Zizania* rice is relatively high in protein when compared with other cereals, a good source of the B vitamins, thiamin, riboflavin, and niacin, and contains common mineral elements in amounts comparable to those in oats, wheat, and corn. Hocking (1997) added that, apart from being a popular side dish in restaurants and groceries, with or without Old World rice (*Oryza saliva*), it is also used in hash, sauces, and seafoods. He noted that medicinally *Zizania* was made into a gruel and mixed with wild licorice tea to treat cholera (Hocking 1997), but he failed to tell by whom.

## *Zizia*

(Named for Johann Baptist Ziz, 1779–1829, a botanist of the Rhine region of Germany)

### *Zizia aurea* (golden)

golden Alexander(s) (“Alexanders” is a name given to *Smyrnum* in Europe; perhaps the name is a corruption of *olus atrum*, black oil, but the presence of *alexandre* about A.D. 940 seems to contradict that view; French *alexandre* is cognate; “golden” was added to distinguish the American from the Old World plants)

golden zizia (a book name)

[golden] meadow parsnip (“parsnip” is corrupted from Middle English *passenep*, ultimately from Latin *pastinaca*, for *Pastinaca sativa*; in use by A.D. 1389; cognate words are German *Pastinak(e)*, Dutch *pastinak*, Italian *pastinaca*, and French *panais*; meadow parsnip was originally in use by 1562 for both a European *Heracleum* and American *Thaspium*; later applied to *Zizia*); *goldene Pastinake* (German, fide Millsbaugh 1892)

wild parsley (“parsley” is from Latin *petroselenium* and Greek *petroselinion*, rock parsley, now *Petroselinum crispum*; cognates are German *Petersilie*, Dutch *peterselie*, Italian *petrosellino*; the name “wild

parsley” has been in use since A.D. 1265 when it was applied to European Apiaceae other than cultivated parsley)

Linnaeus ([1753] 1957) called these plants *Smyrnum aureum*, following the name given to them by Leonard Plukenet in 1696. The name was particularly apt, because he was comparing them with myrrh (Greek *smyrna*) because of the fragrance, and gold (*aurea*) because of the yellow flowers. Linnaeus was using material studied by Jan Gronovius for *Flora Virginica*, Robert Morrison’s list of plants cultivated in England, and specimens grown at the *Hortus Cliffortianus*. Subsequently, Wilhelm Daniel Joseph Koch (1771–1849), a German professor of botany at Erlangen, realized that these American and the European plants were not the same. One of the major differences between the Old and New World plants was that those in Europe were edible, being used as a substitute for celery and parsnips. The American *Smyrnum aureum* was inedible. There are seven Old World species of *Smyrnum* (Mabberley 1997).

In 1825, Koch segregated out the American plants and put them in *Zizia*. Golden Alexanders grows from Saskatchewan and Quebec to New Brunswick, New England, Georgia, Florida, Tennessee, Missouri, Oklahoma, and Texas (Fernald 1950). Later other species were found, and there are now four, all endemic to North America (Mabberley 1997).

Only one indigenous tribe was found to have used these herbs. The Meskwaki powdered Philadelphia fleabane (*Erigeron philadelphicus*) and golden Alexander, used it as a snuff to stop headache, and took the roots to reduce fevers (Gilmore 1919, Vogel 1970).

Among Europeans visiting the New World, this herb was apparently first spoken of by Rafinesque (1830) as vulnerary, antisyphilitic, and sudorific. Millspaugh (1892) knew of a young lady who had eaten a large root and subsequently vomited violently. He thought that, because she ejected the root, she was spared any other toxic action. Later, he experimented on himself with the plants and those experiences made him wonder about its safety. He wrote that his “tongue felt fuzzy and numb. This sensation was followed by a feeling as if the tongue had been scalded with hot tea; my eyes began to water and smart; I ceased writing, and threw myself upon my lounge (12 M); my face then began to feel suffused with blood and soon became hot, especially the cheeks and forehead; drowsiness followed, and I fell into a distressingly dreamy sleep, lasting an hour. When I awoke (1:30 P.M.) all my symptoms had passed away except the scalded sensation of the tongue, which lasted fully an hour longer.”

Foster and Duke (1990) wrote, “Amateurs fooling with plants in the parsley family are playing herbal roulette.” Their comment was written specifically for this species, but it applies to the whole family.

In spite of all these adverse reactions to golden Alexander, the root is still used as a diuretic in European homeopathy (Hocking 1997). Probably it is fortunate that Bremness (1994), Bown (1995), and Duke et al. (2002) do not list the species.

There are comparatively few reports of chemicals in *Zizia*, but *Z. aptera* has coumarins (Schramm 1978) and the glucoside apterin (Steck and Wetter 1974). Hocking (1997) recorded that *Z. aurea* contains aromatic volatile oils.

***Zornia***

(Named for German apothecary Johannes Zorn, 1739–1799)

***Zornia bracteata*** (with bracts on the inflorescence)

bracted zornia (a book name)

cinquefoil (five-finger, from French; usually used for *Potentilla*); five-finger grass

*viperina* (little viper, Florida, Texas)

Plants now known as *Zornia* began in confusion. Except for the Florida species, most of us still find the names baffling.

Relatives of Florida's *viperina* appeared in the European literature at the same time from opposite sides of the world. Hedrik van Rheedee used the Indian name *nelam-mari* (Malayalam) in the 1690s, and at the same time Hans Sloane described them from Jamaica

***Zornia bracteata*.** From Britton and Brown 1897.

under the Latin *Hedysarum minus diphyllum* (the smallest *Hedysarum* with two leaves). Later both N.L.Burmman and Linnaeus studied specimens for flora of Ceylon, and finally Linnaeus called them *Hedysarum diphyllum* in 1753. Oddly, Linnaeus ([1753] 1957) said that they were only found in India (*habitat in Indiis*). Unhappily, that lapse set the stage for continued confusion regarding what became the genus *Zornia*, because he had included two species under one name. Now the Indian plants are *Z. diphylla*, and the Jamaican plants are *Z. reticulata*

It was not until 1792 that the genus *Zornia* was named by J.F.Gmelin in the 13th edition of *Systema Naturae*. The species he used to establish the genus was *Z. bracteata*. That plant grows from Virginia through Florida and into eastern Texas (Fernald 1950, Mohlenbrock 1961, Correll and Johnston 1970). Small (1933) indicated that the species grew in Mexico, but neither Mohlenbrock (1961) nor floras indicate that. Now *Zornia* is considered a genus of 86 species in the warm parts of the world, with 19 species endemic to Australia (Mabberley 1997).

*Zornia bracteata* has been used as a diuretic and laxative (Hocking 1997). Those are the same uses for the widespread *Z. gemella*. Given the incredible confusion in the scientific names and species limits, perhaps all American species are used interchangeably. Most of the records of American plants are under the name *Z. diphylla*, but recent studies suggest that the correct name is *Z. gemella*. This herb grows in Texas, New Mexico, Arizona, and south through Mexico (at least Durango, Jalisco, Oaxaca, Queretaro, San Luis Potosí, Sinaloa, Sonora, Zacatecas) and Central America to Argentina and Paraguay. The legume also grows in Cuba (Leon and Alain 1946–1953) but not in the other islands of the Antilles. Adams (1972) referred Jamaican plants to *Z. reticulata*. Other names for this species are *alverjilla* (sweet pea, Argentina), *barba de burro* (donkey beard, El Salvador), *cargadita* (little strong one, Colombia), *encarrujada* (curly one, Venezuela), *hierba de pujo* (puke herb, Venezuela), *urinaria* (urine maker, Brazil), and *zarzabacoa de dos hojas* (two-leaved trefoil, corrupted from *guasabacoa*, the Taino name, Puerto Rico).

Roig (1945) found the species called *trencilla* (adornment) in Cuba, where it was used to treat dysentery and fever, and as a diuretic. Martínez (1969) and Ford (1975) noted that *Z. diphylla* is called *hierba de la víbora* [*yerba de la víbora*] (viper herb) in Mexico, and that it was used to lower fever. Rojas et al. (1999) found the Otomí of Mexico using it against gastro-intestinal disorders. Pérez-Arbelaes (1978) says that *Z. gemella* is used in Panama and Brazil to stop dysentery and lower fever, and that it is diuretic. Morton (1981) listed identical medical uses in Panama, El Salvador, Costa Rica, Guatemala, and elsewhere in Central America, and in Brazil.

Study by Rojas et al. (1999) suggested that the extracts from at least *Z. gemella* “tend to support ethnomedical use of the plants for the treatment of gastrointestinal disorders.” The presence of other bioactive compounds in the genus is suggested by the name *maconha branca* (white marijuana) recorded for *Z. latifolia* in Brazil by Ghilleen T. Prance et al. (Von Reis and Lipp 1982). Kloos et al. (1987) found that leaf extracts of *Z. setosa* killed 100% of the *Biomphalaria pfeifferi* snails in their study of African plants.
